23 **Abstract**  
24

25 Butter oil (ghee) derived from cow or buffalo milk is in semi-solid form at room temperature  
26  
27 and contains >99% of lipids. Apparent high viscosity and water immiscibility – owing to the  
28  
29 hydrophobic nature of lipid components hinder the applicability of butter oil for formulations.  
30  
31 Here, we have employed ultrasonic processing technique to create oil-in-water emulsions of  
32  
33 butter oil. We show that the butter oil is capable of self-stabilizing an emulsion at low  
34  
35 concentration while higher concentrations could be kinetically stabilized using pluronic  
36  
37 stabilizer. We were able to modulate water contents of emulsions in the range of 80-95% and  
38  
39 maintain the particle size in submicron range. Reported butter oil emulsions retain  
40  
41 hydrophobic properties of the original butter oil within cores of dispersed particles, overcome  
42  
43 a problem of butter oil-water immiscibility, display fluid consistency and are stable for  
44  
45 several months. These properties are highly suitable for developing food, pharmaceutical and  
46  
47 cosmetic formulations.

## Practical Applications

Ultrasonic processing of butter oil improves its miscibility with water and increase its fluidity thereby enhancing its capability to be used as or to derive formulations for various applications. Further advantage of the reported butter oil emulsions is that they can be loaded with 'polar' in addition to 'non-polar' active molecules, which was hardly possible with formulations merely based on butter oil. This is because an aqueous phase of the butter oil emulsion contains 80-95% water where polar molecules can easily be solvated. These emulsions, prepared from quite an abundant and economical source, can potentially act as alternatives to the emulsions that usually involve highly expensive lipid components whose extraction or synthesis are rather tough tasks. The ultrasonic processing of butter oil, presented here, could be easily scaled-up using continuous processing modes.

## Keywords

butter oil, ghee, oil-in-water emulsion, butter oil emulsions, lipid based formulations

## 1. Introduction

Butter oil, also called 'ghee' or 'clarified butter' contains >99% lipids (USDA, 2016) that are often in the semi-solid form at room temperature (Fatouh et al., 2003). It is usually prepared from a butter generated from cow or buffalo milk (Fatouh et al., 2003; Sharma, 1990; Sujatha and Sarashetti, 2015). As compared to other oils, the butter oil can be advantageous, for instance, for high temperature cooking because it has very high smoking point (~150 °C)(The Culinary Institute of America and Donovan, 1995). Moreover, it has a long shelf life and can be stored at room temperature for 6-8 months (Acharya, 1997; Sserunjogiab et al., 1998). The apparent reason for an extended shelf-life is that it contains very less amount (~0.5%) of

moisture and milk solids – some of which naturally exhibit anti-oxidant properties (Sserunjogi et al., 1998) (Fig. 1). Butter, the precursor of the butter oil contains ~18% moisture (Fig. 1) which is evaporated during the hot (>100 °C) preparation of butter oil whereas ~1% milk solids are removed by separation techniques (Acharya, 1997).

*Ayurveda*, a traditional (Indian) medicinal knowledgebase, has referred butter oil as a therapeutic agent (Cope et al., 1996; Heyn, 1987; Pariza, 1991; Sujatha and Sarashetti, 2015; Tirtha, 1998) to treat skin diseases and allergies. Over the years, the butter oil has been used as a suitable medium for preparation of various *Ayurvedic* - herbal and cosmetic formulations (Bishwas, 2013; Lad, 1999; Liu, 2014; Shah, 2014). It was found to be a superior vehicle for lipophilic herbs as compared to other formulation types such as tablets and powders ((Lad, 1999; Sharma, 1990). However, to extend this application arena further, it is necessary to develop reliable, reproducible and consistent formulations from butter oil. But the difficulties arise due to its highly lipophilic nature. Although butter oil can solubilize lipophilic drugs in it, their efficient delivery is challenged because of the immiscibility with water. One of the effective solutions is believed to be the emulsification of butter oil in aqueous media. Previous reports demonstrate that it is possible to kinetically stabilize butter oil in the form of emulsions using stabilizers such as sodium caseinate (Sangwan et al., 2000), polyvinyl alcohol (Saravanan et al., 2007) and Tween 60 (Newton et al., 2015). In this work we have prepared oil-in-water (o/w) emulsions of butter oil using a tri-block copolymer - pluronic® F127, which was not used previously for this purpose. This stabilizer has been quite successful for stabilizing a range of lipid based emulsions (Engelskirchen et al., 2011; Nakano et al., 2002; Yaghmur et al., 2005) and hybrid systems developed from them (Kulkarni and Glatter, 2012; Kulkarni et al., 2015; Kulkarni et al., 2011a). These systems have already demonstrated their potential as efficient drug carriers for poorly water soluble

1  
2  
3 drugs (Chong et al., 2015). Similarly butter oil emulsions, presented here, are quite promising  
4  
5 for formulation applications.

## 8 9 **2. Materials and Methods**

### 10 11 **2.1 Materials**

12  
13  
14 Unsalted butter (“unsalted English Butter” by Sainsbury’s, UK; Batch 01117011) was  
15  
16 purchased from the supermarket and used to prepare butter oil without further  
17  
18 treatment. The emulsion stabilizer, triblock copolymer Pluronic® F127 (PEO99-  
19  
20 PPO67-PEO99) was purchased from Sigma-Aldrich, UK. Water used during entire  
21  
22 work was purified using Barnstead Nanopure, Thermoscientific (USA).  
23  
24  
25  
26  
27

### 28 29 **2.2 Preparation of butter oil**

30  
31 Butter oil was prepared in the following steps: unsalted butter (as mentioned above)  
32  
33 was melted on a gentle heat (~70 °C), subsequently the temperature was raised above  
34  
35 ~95 °C to evaporate the moisture (for ~10 min) followed by the reduction of the heat  
36  
37 down to ~70 °C. The heating was stopped completely when bubbles fade away and  
38  
39 solid residues start turning brown. Appearance of characteristic (pleasant) odour  
40  
41 signifies that the butter oil is ready. Transparent yellow fluid was then separated from  
42  
43 solid residues (brown) by decanting and/or by filtration. This fluid, i.e. the butter oil,  
44  
45 was stored at room temperature in its partially solidified form.  
46  
47  
48  
49  
50

### 51 52 **2.3 Preparation of butter oil emulsions**

53  
54 Butter oil emulsions were prepared using similar protocol as published for lipid  
55  
56 emulsions (Kulkarni et al., 2015) but with slightly different parameters. 500 mg of  
57  
58 molten butter oil was added to the 20 ml scintillation vial (VWR International Ltd)  
59  
60

1  
2  
3 followed by an addition of 9.5 gm of water to make total weight of 10 gm. The  
4  
5 mixture was then subjected to an ultrasonic processing (Sonics & Materials Vibra-Cell  
6  
7 VCX750, Jencons, UK) for 10 min at an intermittent pulse of 1 sec with 1 sec delay  
8  
9 time using 35% of the maximum power. Milky white emulsion (containing 5 wt%  
10  
11 butter oil), formed within minutes, was then allowed to cool at room temperature.  
12  
13 Emulsions of 10, 15 and 20 wt% (note: now on wt% will be designated as % unless  
14  
15 stated differently) of the butter oil were prepared in the same manner as discussed  
16  
17 above; corresponding butter oil concentrations were 1000 mg, 1500 mg and 2000 mg  
18  
19 making total weight of 10 gm with water. Emulsion photos were taken by 8.0  
20  
21 megapixel camera from iPhone 5 against white backgrounds.  
22  
23  
24  
25  
26  
27

28 **2.4 Preparation of butter oil emulsions using pluronic F127 stabilizer**

29  
30 Mere 0.5% pluronic F127 stabilizer solution (in water) was sufficient to produce stable  
31  
32 emulsions as shown in Fig. 3. These emulsions were prepared using the same ultra-  
33  
34 sonic processing parameters as mentioned above (section 2.3).  
35  
36  
37  
38

39 **2.5 Small angle X-ray scattering**

40  
41 Small angle X-ray scattering (SAXS) was utilized to study the nanostructural features  
42  
43 of the butter oil and its emulsions. Details of the instrument and the analysis protocol  
44  
45 are published earlier (Patil-Sen et al., 2016). The SAXSpace (Anton Paar, Graz,  
46  
47 Austria) instrument with Cu-K $\alpha$  radiation at a wavelength ( $\lambda$ ) of 0.154 nm was used in  
48  
49 the high resolution mode to detect a minimum scattering vector,  $q_{min}$ , of 0.04 nm<sup>-1</sup> ( $q =$   
50  
51  $(4\pi/\lambda)\sin\theta$ , where  $2\theta$  is the scattering angle). Samples were prepared in 1 mm quartz  
52  
53 cell (Anton Paar, Graz, Austria) and studied under vacuum and temperature (25±0.1  
54  
55 °C) controlled environment. Three images of typical exposure times of 300 sec were  
56  
57  
58  
59  
60

averaged to obtain 1D scattering profiles which were then analysed using The SAXStreat software (Anton Paar, Graz, Austria) (Patil-Sen et al., 2016).

## 2.6 Particle size by Mastersizer

The particle size and the particle size distribution of emulsions were determined using a static light scattering equipment called Mastersizer 3000 (Malvern Instruments Ltd, Malvern, UK).

## 2.7 Scanning electron microscopy

Morphological features of butter oil emulsions were examined using scanning electron microscopy (SEM) (FEI, Quanta). Samples were studied in a) fluid state using environmental attachment (at 15 °C), b) freeze-dried (Scanvac, Coolsafe) form (at 8 °C), and c) in vacuum dried form (at 8 °C) with high-vacuum option in SEM. The latter two were gold-sputtered for 35 seconds.

# 3. Results and discussion

## 3.1 Self-stabilized emulsions of butter oil

Among the range of butter oil emulsions (5%, 10%, 15% and 20%) prepared, only 5% emulsions were stable for more than 30 min whereas others undergo rapid phase separation (Fig. 2). There are some fundamental reasons behind the instability of these self-stabilized butter oil emulsions (self-stabilization: butter oil acting as an emulsion stabilizer). First, the butter oil is composed of more than 99% lipids, which usually have a limited solubility in water (Newton, 2014). Second, there is about two orders of magnitude difference in their viscosities (viscosity of the butter oil is ~45 mPa.s

(Bürkle GmbH, 2011) while the viscosity of water equals to 0.65 mPa.s (Korson et al., 1969) measured at 40 °C). Moreover, some of the lipids in butter oil start solidifying when cooled below 40 °C promoting further phase separation (Deshpande and Kulkarni, 2012; Sulieman et al., 2013). These features hinder the self-stabilization of butter oil emulsions. Due to its low density ( $\sim 0.93 \text{ gm/cm}^3$ ) (Deshpande and Kulkarni, 2012; Sulieman et al., 2013), the butter oil floats on the water as shown in Fig. 2 (indicated by block arrows). In addition, the local phase separation contributes towards formation of oily droplets. Such droplets were (partly) visible in high butter oil emulsions giving them the yellow tinge (Fig. 2).

### 3.2 Kinetic stabilization of butter oil emulsions

Some of the aforementioned problems, causing emulsions' destabilization, can be overcome by using stabilizer molecules ((Garti et al., 1993; Kulkarni and Glatter, 2012; Sjoblom, 2005). The process is called 'kinetic stabilization', where the emulsion is kept stable over time thereby significantly decreasing common destabilization parameters such as droplet coalescence, creaming or Ostwald ripening (Sjoblom, 2005). Sterically modulated physicochemical forces between the droplet interfaces create a barrier preventing their aggregation, thus enhancing kinetic stability of an emulsion. We used a (food grade) non-ionic tri-block co-polymer pluronic® F127 (MW=12.6 kDa) to stabilize butter oil emulsions. This is an amphiphilic molecule formed of two blocks of (PEO)<sub>99</sub> and one block of (PPO)<sub>67</sub> imparting hydrophilic and hydrophobic characters to the molecule, respectively (Desai et al., 2001). The hydrophobic block interacts with the hydrophobic chains of lipid molecules that usually self-assemble into inverse (*type 2*) (Kulkarni et al., 2011b) micelles, while the

hydrophilic blocks face towards aqueous medium thereby enhancing the dispersibility of oil droplets/particles (Fig. 3a).

The viscosity of the kinetically stabilized emulsions was found to increase virtually once they cool down after sonication as well as with increasing the butter oil concentration. The consistency imparted due to the viscosity difference ranged from water-like to creamy, in nature. This can be attributed to the solidification of lipids, whose melting point lies around 37 °C (Deshpande and Kulkarni, 2012; Sulieman et al., 2013). Despite of this, stable and reproducible emulsions could be prepared up to 15% of the butter oil (Fig. 3b, c, d) while the 20% sample struggled to stay stable after about an hour (Fig. 3e). Nevertheless, the separated oil in the latter was completely re-dispersed upon gentle shaking (explained later in Fig. 7).

### 3.3 Nano-micro structural characterization of butter oil emulsions

Small angle X-ray scattering was used to determine the type of phase (nanostructure) exhibited by butter oil lipids. At 25 °C, undispered butter oil showed lamellar nanostructure in presence of water, as evidenced from the typical peaks in Fig. 4 (shown by block arrows); the d-spacing was found to be  $41.5 \pm 0.5$  Å. Two little peaks (Fig. 4, shown by stars) were observed for kinetically stabilized emulsion which may mean that the partial order is still retained inside the stabilized particles. Typical upturn in the low  $q$  region with scattering intensity  $I(q) \propto q^{-2}$  indicate the formation of particulate structures (Fig. 4) (Pearce et al., 2014). However, there was no characteristic signal seen in self-stabilized emulsions, presumably depicting the partial aggregation. This was also supported by the observation of rather wide particle size distribution (studied by Mastersizer) in self-stabilized emulsions (Fig. 5). Kinetically

stabilized emulsions, on the other hand, exhibited sub-micron sized particles with relatively narrow size distribution (Fig. 5). Particle size and microstructure of kinetically stabilized emulsions was also confirmed with SEM micrographs as shown in Fig. 6.

3.4 Stability and shelf-life of butter oil emulsions

As mentioned earlier, 5% emulsions were stable with and without stabilizer. Butter oil in higher concentrations, however, became separated within an hour in case of the emulsions prepared without stabilizer (see Fig. 2). Kinetic stabilization (using stabilizer) improved the stability of butter oil emulsions up to about a month. After which these emulsions looked as shown in Fig. 7a where some of the butter was seen to be forming a layer on the top (indicated by arrows). The thickness of the layer increased with the concentration of butter oil. Nevertheless, the separation was significantly less as compared to the separation in Fig. 2, which is evident from the color of the separated layer (dark yellow in Fig. 2 while pale yellow in Fig. 7a). More importantly, all of these emulsions could be made homogeneous again upon gentle shaking (2-3 upside down moves), as shown in Fig. 7b. Emulsions were stable, in this manner, for at least studied six months. The shelf-life of these emulsions was observed for about six months (at room temperature) during which there was no characteristic odor or growth of fungus demonstrating the degradation of the butter oil; for instance, similar to the Mendez-Vilas report (Méndez-Vilas, 2012).

#### 4. Conclusions and Perspectives

Oil-in-water emulsions, from high lipid (>99%) containing butter oil, were prepared using an ultrasonic processing technology. Being itself a food material, the butter oil clearly exhibits biocompatibility and food grade properties, therefore the emulsions reported here are highly suited for potential biotechnological applications. Butter oil emulsions provide a number of advantages as compared to the bulk butter oil; for instance, the flavour (sometimes unwanted) generated during the preparation of butter oil via Maillard reaction (Newton, 2014; Newton et al., 2015) is significantly reduced upon its emulsification. These emulsions contain a very high (80% to > 95%) concentrations of water thereby improving their applicability in formulation sector by enabling the use of aqueous phase to solubilize hydrophilic molecules along with the lipophilic ones - solubilized in the cores of lipid particles (Kulkarni and Glatter, 2012). In addition, these emulsions have a range of (fluid to creamy) consistencies which can be finely controlled with the lipid contents. Further characteristics, including long term stability, extended shelf life, submicron sized particulate form and variable viscosity, facilitate the butter oil emulsions to be exploited for various pharmaceutical and cosmetic formulations. As compared to the lipids that are commonly used for preparing poorly soluble drug formulations, the butter oil lipids are rather cheap and easily available. Therefore, butter oil emulsions find great potential for formulation based applications. To summarize, the reported butter oil emulsions: 1) retain hydrophobic properties of the original butter oil at the cores of dispersed particles, 2) overcome a problem of butter oil-water immiscibility, 3) display fluid consistency, 4) exhibit enormous interfacial area as well as aqueous region, 5) are easy to prepare reliably, and 6) are stable for several months. These properties are highly suitable for developing food, pharmaceutical and cosmetic formulations.

**Acknowledgements**

We would like to thank Ms. Sana Sayed for the experimental work on butter oil emulsions, while Prof Michael Rappolt and Dr Amin Sadeghpour from the School of Food Science & Nutrition, University of Leeds, Leeds, UK for allowing us to use SAXS and Mastersizer facilities. Also thanks to Dr Yogita Patil-Sen who and Amin performed experiments on above facilities. We kindly acknowledge Ms. Priti C. Kulkarni for assisting us with the preparation of butter oil.

Fig. 1 Main constituents of butter (a) and butter oil (c) shown in percent weights; the data obtained from USDA, National Nutrient Database for Standard Reference Release 28. (USDA, 2016). Schematic of the preparation of butter oil from butter (b); images courtesy Priti C. Kulkarni. 20x6mm (300 x 300 DPI)

Fig. 2 Butter oil was able to self-stabilize its emulsion at low concentration, that is 5% as shown in a) while it was phase separated in all higher concentrations as shown by arrows in b), c) and d) respectively for 10, 15 and 20% butter oil emulsions. Images were captured after 30 min of their preparation.  
20x7mm (300 x 300 DPI)

Fig. 3 a) Schematic drawing depicts the role of stabilizer (F127) in dispersing the oil droplets/particles in o/w emulsion. Kinetically stabilized o/w emulsions with 5, 10, 15 and 20% butter oil are shown in b), c) d) and e) respectively. Emulsions were stable up to 15% butter oil content, while 20% butter oil emulsion started phase separating after about an hour.  
16x3mm (300 x 300 DPI)

Fig. 4 Small angle X-ray scattering studies revealed the presence of lamellar nanostructure (peaks indicated by arrows) in the hydrated butter oil sample while no peak was observed for self-stabilized emulsions. Kinetically stabilized particles showed typical upturn in low  $q$  region with tiny peaks (shown by \*) located around the first order peak of the lamellar nanostructure of the hydrated butter oil sample.

17x11mm (600 x 600 DPI)

Fig. 5 Particle size analysis elucidates the narrow size distribution in case of kinetically stabilized emulsions as compared to the self-stabilized emulsion. Emulsions used for performing SAXS and particle size measurements contained 5% butter oil.  
20x13mm (600 x 600 DPI)

Fig. 6 Scanning electron microscopy (SEM) micrographs of butter oil emulsions in a) fluid state, b) freeze-dried form and c) high vacuum mode in SEM. The particle size in the micron range is evident from all of these images.

57x156mm (300 x 300 DPI)

Fig. 7 Emulsions with high concentration of butter oil ( $\geq 10\%$ ) partially destabilized after about a month as shown in a), which were homogenised again after gentle shaking as in b). Arrows indicate the butter oil layer formed in the upper part of emulsions. Re-dispersion of the emulsions (by gentle shaking) could be effectively done for at least six months (of study time).  
40x34mm (300 x 300 DPI)
