Abstract

A novel oligomer (PFDCHQ) based on 9,10-dihydro-9-oxa-10-phosphaphenanthrene -10-oxide (DOPO) and ferrocene groups was synthesized successfully, aiming at improving the flame retardant efficiency of diglycidyl ether of bisphenol A epoxy resin (DGEBA). FTIR, ¹H NMR and ³¹P NMR were used to confirm the chemical structure of PFDCHQ. The high char yields of 60.3 wt% and 20.1 wt% were obtained for PFDCHQ from TGA results in nitrogen and air atmosphere, respectively. The thermal degradation mechanism of PFDCHQ was investigated by TG-FTIR and Py-GC/MS. The limiting oxygen index (LOI) of EP-5 with 5 wt% loading of PFDCHQ increased to 32.0% and the UL-94 V-0 rating was achieved, showing a notable blowing-out effect. In contrast to EP-0, the peak of the heat release rate (pHRR) and total heat release (THR) of EP-5 decreased by 18.0% and 10.3%. The flame retardant mechanism of PFDCHQ in epoxy resin was studied by TG-FTIR, SEM and Raman. SEM and Raman results indicated the formation of coherent and dense char residue with high degree of graphitization due to the incorporation of PFDCHQ. In UL-94, the blowing-out effect dominantly accounted for the enhanced flame retardancy in combination with optimized char structure. Furthermore, the addition of PFDCHQ improved the Young's modulus compared to EP-0.

Keywords: DOPO-HQ; Ferrocene; Synthesis; Epoxy resin; Flame retardant mechanism

1. Introduction

Epoxy resin (EP) is widely applied in many areas such as coating, adhesive, laminating, electronic/electrical insulation, and composite application [1-3], due to its excellent mechanical properties, chemical stability, bonding behavior and abundant product forms [4-6]. However, the high flammability is a general shortcoming of EP and limits its applications. Therefore, it has attracted more and more attention to endow EP with required flame-retardance.

As an important halogen-free flame retardant, phosphorus flame retardants (PFRs) [7, 8] have attracted extensive attention [9-11] for their high efficiency. Most of the PFRs not only play flame retardant effects through a protective char layer caused by the catalyzation of phosphoric acid [12, 13], but also play flame retardant role in the gas phase through the radical trapping by PO and PO₂ fragments [14, 15]. In recent years, 9,10-dihydro-9-oxa-10-phosphaphenanthrene-10-oxide (DOPO) and its derivatives, as a novel kind of PFRs, have received considerable attention attributed to their high reactivity [16]. When DOPO-based PFRs are applied in epoxy resin, it is often used in conjunction with nitrogen/silicon elements as small molecular PFRs [17-19]. However, the non-polymeric PFRs display many drawbacks such as poor compatibility with polymer matrix and easily leaching. Comparatively, DOPO-containing polymeric flame retardants not only have higher phosphorus content and richer aromatic group structures, but also can overcome these shortcomings of small molecular PFRs [20, 21].

The 10-(2,5-Dihydroxyphenyl)-10H-9-oxa-10-phospha-phenanthrene-10-oxide (DOPO-HQ) is one of the most important derivatives of DOPO. The two hydroxyl groups in DOPO-HQ molecule can react with other active function groups to form polymeric phosphorus-containing flame retardants, which have good compatibility with epoxy resin and are not easily migrated during the processing or using according to the published literature [22, 23]. Wang et al. synthesized a polymeric PFR based on 10-(2, 5-dihydroxyl-phenyl)-9, 10-dihydro-9-oxa-10-phosphaphenanthrene-10-oxide (DOPO-BQ) and pentaerythritol diphosphonate dichloride (SPDPC), a V-0 rating in the UL-94 test was obtained with PFR content of 10 wt% in epoxy resin [24]. Carja et al. reported a new phosphorus flame retardant by solution polycondensation of 1,4-phenylenebis phenylenebis ((6-oxido-6H-dibenz[c,e][1,2]oxaphosphorinyl) carbinol) with phenylphosphonic dichloride, and a UL-94 V-0 rating material was obtained when 14.8 wt% PFR were added into the epoxy matrix [23]. In addition, Tian et al. synthesized a novel organophosphorus named as poly(4,4-dihydroxy-1-methyl-ethyl diphenol-o-bicyclic pentaerythritol phosphatephosphate) (PCPBO) and achieved good flame retardant epoxy resin composites with the formation of an intumescent char layer [25]. However, the high loadings was needed to reach the V-0 level due to the poor catalytic effect of phosphoric acid and the low flame-retardant efficiency when these reported polymeric PFRs were used in epoxy materials. Therefore, it is a preferable idea to introduce a functional group with high-effective catalyzing function onto PFR molecules for more char formation. It is already known that transition metals including Fe, Co and Ni can cause catalytic char-formation of polymer [26-28]. So, it is a promising way to combining iron-containing unit with phosphorus-containing unit.

Ferrocene has received considerable attention due to its effective smoke suppression and catalyzing crosslinking performance [29, 30]. The previous reports revealed that some polymers containing ferrocene and phosphorus had high char yield and thermal stability [31, 32]. Kishore et al. synthesized a series of polyphosphate esters containing ferrocene. Theses polyester-phosphate esters (VI, VII, VIII, IX and X) provided high char residues of 28%, 38%, 27%, 23% and 32% at 700 °C [33]. Mehdipour-Ataei reported a battery of ferrocene-based polyamides and had high char yield from 43% to 72% at 600 °C [34]. Besides, Liao synthesized a novel ferrocene-based copolymer with 62 % char residue at 700 °C under nitrogen. When applied it in epoxy resin, a UL-

94 V-1 rating and LOI value of 29.2% are obtained, which is attributed to the excellent catalytic charring capacity of ferrocene-based copolymer [35].

Combined the merits of DOPO and ferrocene groups, a novel oligomeric flame retardant poly 10-(2,5-dihydroxyphenyl)-9,10-dihydro-9-oxa-10-phospha Phenanthrene-10-oxide-1,1'-ferrocene dimethyl ester (PFDCHQ) containing DOPO-HQ and ferrocene was synthesized and incorporated into diglycidyl ether of bisphenol A epoxy resin (DGEBA) to improve its fire retardancy. The chemical structure of PFDCHQ was characterized by FTIR, ^1H NMR and ^{31}P NMR. The fire retardancy, flame retardant mechanism and mechanical properties of EP/PFDCHQ composites were comprehensively studied. The results show that PFDCHQ is a kind of high-effective flame retardant for epoxy resin material.

2. Experimental

2.1. Materials

Ferrocene (98%), oxalyl dichloride (98.0%) and methylene dichloride (CH_2Cl_2 , 99.5%) were purchased from Sinpharm Chemical Reagent Co. Ltd. (China). DOPO-HQ (Huizhou sunstar technology Co. Ltd., China) was used without further purification. Sodium hypochlorite solution (active chlorine is 10%) was provided from Shanghai Aladdin Biochemical Technology Co. Ltd. (China). Petroleum ether was provided by Tianjin Zhiyuan Chemical Reagent Co. Ltd. (China). Epoxy resin (DGEBA, commercial name: E-44, with an epoxy value of 0.41-0.48) was supplied by Nantong Xingchen Synthetic Material Co. Ltd. (Jiangsu China). The curing agent m-Phenylenediamine (m-PDA) was purchased from Tianjin Guangfu Co. Ltd. (China).

2.2. Preparation of PFDCHQ

2.2.1. Synthesis of 1,1'-diacetylferrocene (DAF)

In a 500 ml three-necked flask with a magnetic stirrer, flux condenser and nitrogen inlet, AlCl_3 (46.7 g, 0.35 mol) and 125 ml CH_2Cl_2 were introduced into it. The mixture was stirred at room temperature for 5 min. Then, the AlCl_3 was dissolved after adding 107 ml acetyl chloride dropwise through dropping funnel. Next, ferrocene (18.6 g, 0.1 mol, dissolved in 100 ml absolute CH_2Cl_2) was added dropwise. The reaction mixture was stirred at room temperature for 2 h and the dark purple solution was produced. Afterwards, the solution was slowly poured into lots of ice. The organic phase and water phase were separated with a separating funnel. After that, the organic phase was washed with water and extracted, repeatedly three times, then the CH_2Cl_2 was rotary evaporated. The crude product was purified by petroleum ether until the washing liquid was colorless. Finally, recrystallization from water gave 20.25 g (yield: 75%) of red acicular crystal, which was named as DAF. FT-IR (KBr, cm^{-1}) ν : 3435 (H_2O); 3094 (Cp-H); 1660 ($-\text{C}=\text{O}$); 2980, 1456 and 1375 ($-\text{CH}_3$); 1297, 1150, 842, 542 and 502 (Cp ring). ^1H NMR (600 MHz, CDCl_3 , δ , ppm): 4.51 (4H, s, Cp), 4.77 (4H, s, Cp), 2.35 (6H, s, $-\text{CH}_3$). The corresponding spectra are shown in Fig. S1.

2.2.2. Synthesis of 1,1'-Ferrocenedicarboxylic acid (FDC)

DAF (13.3 g) was added to 350 ml of 10% sodium hypochlorite solution at 65 °C and rapid stirred in the dark. A further 200 ml of sodium hypochlorite solution was added after 2 h, and kept rapidly stirring for 6 h at 65 °C. Then the reaction solution was filtered hot and acidified to pH 1-2

with concentrated hydrochloric acid, forming a copious orange precipitation. The crude product was filtered, next dissolved in sodium hydroxide solution, and subsequently, reacidified with concentrated hydrochloric acid and precipitated to obtain pure orange 1,1'-ferrocenedicarboxylic acid, which was named as FDC (10.8 g, yield: 81 %). FTIR (KBr, cm^{-1}) ν : 3435 (H_2O), 3200-2500 (association of $-\text{OH}$), 1688, 1302 (COO) [36]; 1492, 1169 and 841 (Cp ring); 1405, 919 (O-H); ^1H NMR (600 MHz, $\text{CH}_3\text{COOH-d}_4$, δ , ppm): 4.57 (4H, s, Cp), 4.93 (4H, s, Cp), 11.59 ($-\text{COOH}$). The FTIR and ^1H NMR spectra are shown in Fig. S2.

2.2.3. Synthesis of PFDCHQ

1,1'-Ferrocenedicarboxylic chloride was prepared according to previous work [37]. In a 500 ml three-necked flask equipped with a magnetic stirrer and condenser, FDC (13.0 g), CH_2Cl_2 (200 ml), oxalyl chloride (20 ml) and 10 drops of pyridine were added and the reaction mixture was stirred at room temperature for 12 h. Subsequently, the mixture was heated to reflux temperature for 6 h. Then, the solvent and unreacted oxalyl chloride were removed by rotary evaporation under reduced pressure to obtain crude product. Finally, the crude product was extracted repeatedly with hot petroleum until the petroleum is colorless and the crimson product was obtained, which is named as 1,1'-Ferrocenedicarboxylic chloride.

DOPO-HQ (0.03 mol) was dispersed in 150 ml absolute CH_2Cl_2 and added into a 500 ml three-necked round-bottom flask equipped with a magnetic stirrer, condenser and constant pressure dropping funnel. Next, Et_3N (8.3 ml) was introduced into the mixture and stirred at room temperature for 10 min. Thereafter, 1,1'-ferrocenedicarboxylic chloride (0.03 mol), which was dissolved in 50 ml CH_2Cl_2 , was added dropwise. Moreover, the reaction mixture was stirred at room temperature for 12 h under nitrogen protection. Then, the brown solution was poured into 500 ml methanol with stirring after filtered and washed thoroughly with methanol, the resulting product was dried at 60°C under vacuum to a constant mass (yield: 85 %), which is named as PFDCHQ. The preparation route of PFDCHQ is shown in Scheme 1.

Scheme 1. Synthetic route to PFDCHQ

2.3. Preparation of EP/PFDCHQ composites

Briefly, the preparation of epoxy composites with 5 wt% PFDCHQ was as follows: epoxy resin (50.0 g) and PFDCHQ (2.63 g) were added into a 150 ml flask with 20 ml dry CH_2Cl_2 and stirred 10 min. After a homogeneous mixture was obtained, and then placed to the rotary evaporators at 70°C to remove the CH_2Cl_2 solvent. Next, m-PDA (5.0 g) was added in the mass ratio 10: 1 of EP. After that, the mixture was stirred at 80°C under reduced pressure until no bubbles emerged. Subsequently, it was poured into a preheated standard polytetrafluoroethylene (PTFE) mold at 80°C . The mixture was cured at 80°C for 3 h, 100°C for 2 h and then 120°C for 3 h. After curing, the samples were cooled to room temperature and the EP/PFDCHQ was obtained. The formulas of EP/PFDCHQ composites are listed in Table 1. Other samples were prepared in the same procedure. A schematic representation of the preparation process of EP/PFDCHQ composites is shown in Scheme 2.

Scheme 2. A schematic representation of the preparation process of EP/PFDCHQ composites

2.4. Characterization

Fourier Transformation Infrared Spectroscopy (FTIR) of PFDCHQ and its intermediate on a KBr pellet were analyzed on a FTIR spectrometer (Nicolet 5700) over the wavenumber from 400 to 4000 cm^{-1} .

^1H NMR and ^{31}P NMR spectra were performed on Bruker Avance 600 spectrometer (600 MHz), using DMSO-d_6 as solvent.

The glass transition temperature (T_g) of PFDCHQ with ~5 mg was measured by differential scanning calorimeter (DSC) on Jupiter STA 449C thermal analyzer (Netzsch, Germany) with a heating rate of 10 $^\circ\text{C}/\text{min}$ ranging from 25 $^\circ\text{C}$ to 200 $^\circ\text{C}$ under nitrogen atmosphere.

Table 1. Formulation of EP/PFDCHQ composites

Samples	EP (g)	m-PDA (g)	PFDCHQ	
			(g)	(wt%)
EP-0	50	5.0	-	-
EP-3	50	5.0	1.55	3.0
EP-4	50	5.0	2.08	4.0
EP-5	50	5.0	2.63	5.0
EP-6	50	5.0	3.19	6.0
EP-7	50	5.0	3.76	7.0

The DSCQ2000 (TA Instrument company, USA) was used to study T_g of EP and its composite under nitrogen. All samples were heated from room temperature to 150 $^\circ\text{C}$ at a heating rate 10 $^\circ\text{C}/\text{min}$ and keeping for 5 min, and then cooled to room temperature at -20 $^\circ\text{C}/\text{min}$. A second scanning was conducted at the same heating rate as the first time from room temperature to 150 $^\circ\text{C}$.

The molecular weight and their distribution were determined by Gel Permeation Chromatography (GPC) with an Agilent 1200SERIES instrument using THF as eluent at a flow rate

of 1.000 ml/min.

The thermogravimetric analysis (TGA) of samples with ~5 mg was carried out with STA6000 simultaneous thermal analyzer (PerkinElmer, USA) from 40 °C to 700 °C at a heating rate of 10 °C/min under nitrogen.

The pyrolysis behavior (Py-GC/MS) of the PFDCHQ was tested with DANI MASTER GC-TOF-MS system combined with a pyrolyzer (CDS5200). The samples (~0.3 mg), packed in a quartz tube capillary using the platinum coil attachment, were heated from ambient temperature to 700 °C at a rate of 1000 °C/s and kept at this state for 20 seconds. The Py/GC interface temperature was set at 100 °C. The transfer line temperature was set at 260 °C. The injector temperature was set at 280 °C and operated in the split mode (split ratio 1000: 1) with helium as carrier gas. The detailed data were analyzed using the NIST Mass Spectral Search Program and the NIST library was employed as the standard spectral library to match the volatile pyrolysis product recorded from the analysis.

Thermogravimetric analysis/fourier transform infrared spectra (TG-FTIR) was performed on a STA6000 simultaneous thermal analyzer (PerkinElmer, USA) at a heating rate of 10 °C/min from 40 °C to 700 °C with ~20 mg powder samples under nitrogen atmosphere.

The limiting oxygen index (LOI) values of the samples were measured by a JF-3 oxygen index meter (Nanjing Jionglei Instrument Equipment Co., Ltd) according to the standard of ASTM D 2863-97 with the three dimensions size of $100.0 \times 6.5 \times 3.2 \text{ mm}^3$.

UL-94 vertical burning tests were performed on a vertical burning test instrument (Nanjing Jionglei Instrument Equipment Co., Ltd) based on the standard of ASTM D 3801 with the three dimensions size of $130.0 \times 13.0 \times 3.2 \text{ mm}^3$.

The cone calorimeter test was carried out on a FTT Standard Cone Calorimeter (Fire Testing Technology, UK) according to ISO 5660 under an external heat flux of 35 kW/m² with sample dimensions of $100.0 \times 100.0 \times 3.0 \text{ mm}^3$.

The char residues of EP and EP/PFDCHQ composites after the UL-94 test were investigated on a TM-3000 (Hitachi, Japan) desktop scanning electron microscope (SEM).

The PIT501J LCD plastic Charpy impact testing machine (Shenzhen million Test Equipment Co., Ltd.) was utilized to measure the impact performance of pure EP and EP/PFDCHQ composites with their dimensions of $80.0 \times 10.0 \times 4.0 \text{ mm}^3$, according to GB/T1043-2008. The tensile strength was performed on ETM105D 100 KN computer-controlled electronic universal testing machine (WANCE GROUP) with a testing speed of 20 mm/min, depending on GB/T1040.3-2006.

The fracture surface of EP/PFDCHQ composites was carried on the Ultra55 scanning electron microscope (SEM).

3. Results and discussion

3.1. Characterization of PFDCHQ

The structure of PFDCHQ was confirmed by FTIR, ^1H NMR and ^{31}P NMR. Some specific absorption peaks appear from DOPO-HQ (Fig.1(a)): 1595 cm^{-1} (P-Ph), 1197 cm^{-1} (P=O), 924 cm^{-1} (P-O-Ph) [38]. In case of PFDCHQ, these characteristic peaks still exist. The peaks at $3107, 1583\text{ cm}^{-1}$ (benzene ring) and $1450, 832, 493\text{ cm}^{-1}$ (Cp ring) [39] are clearly observed in the FTIR spectrum of PFDCHQ. In addition, the most significant absorptions are observed at 1737 cm^{-1} and $1092\text{ cm}^{-1}, 1181\text{ cm}^{-1}, 1274\text{ cm}^{-1}$ corresponding to the C=O and C-O-C respectively [12], indicating the existence of ester group. In the ^1H NMR spectrum of PFDCHQ (see Fig.1 (b)), the peaks ranging from 8.09 to 7.10 ppm are ascribed to the protons on the benzene ring. The peaks from 5.50 to 4.01 ppm belong to the protons on the Cp ring. Furthermore, PFDCHQ exhibits a single peak at 33.9 ppm in ^{31}P NMR spectrum (Fig. 1(c)). All the results of FTIR, ^1H NMR and ^{31}P NMR state that PFDCHQ is obtained successfully.

Fig. 1. (a) FTIR spectra of DOPO-HQ and PFDCHQ, (b) ^1H NMR spectrum and (c) ^{31}P NMR spectrum of PFDCHQ

The GPC and DSC curves of PFDCHQ are showed in Fig. S3. The weight average molecular weight (M_w) of PFDCHQ is 10030 g/mol and a number molecular weight (M_n) is 6082 g/mol, accompanied by the polydispersity M_w/M_n of 1.649. The glass transition temperature (T_g) value of $92.4\text{ }^\circ\text{C}$ suggests a relatively high temperature resistance of PFDCHQ.

3.2. Thermal and pyrolysis behavior of PFDCHQ

The TGA/DTG curves of PFDCHQ in both nitrogen and air are shown in Fig. 2. Based on Fig. 2(a), there are two thermal degradation stages. The first one ranges from 230.6 to $326.6\text{ }^\circ\text{C}$, and a weight loss of 5 wt% occurs due to the thermal cleavage of ester bond and the early thermal decomposition of some PFDCHQ with low-molecular weight, generating DOPO and ferrocene-based segments. The main degradation stage takes place from 342.4 to $597.5\text{ }^\circ\text{C}$, accompanied by the temperature of maximum mass loss rate (T_{max}) around $481.2\text{ }^\circ\text{C}$ and a weight loss of 35 wt%. At this stage, the DOPO-based segments are mainly decomposed into dibenzofuran, PO and PO_2 radicals in nitrogen environment due to the lack of oxygen. According to the TG-FTIR data (Fig. 3), partial ferrocene-containing segments begin to decompose above $390\text{ }^\circ\text{C}$. As for the thermal degradation of PFDCHQ in air (Fig. 2 (b)), the more complex thermal-oxide degradation process can be seen. The initial decomposition temperature ($T_{-5\%}$) of PFDCHQ is advanced to $269.1\text{ }^\circ\text{C}$ due to the existence of oxygen. The first main decomposition stage from $218.9\text{ }^\circ\text{C}$ to $523.4\text{ }^\circ\text{C}$ with a

weight loss of 38.5%, including series of thermal degradation stages from DTG curve, can be assigned to the decomposition of low-molecule weight PFDCHQ, cleavage of ester bonds, and the further degradation of ferrocene or phosphorus-containing structures, generating an unstable carbonaceous layer. The second main thermal degradation stage from 523.4-622.5 °C originates from the further thermal-oxide decomposition of the unstable carbonaceous layer. Moreover, the char residues of PFDCHQ in nitrogen and air atmosphere are 60.3 wt% and 20.1 wt% at 700 °C, respectively, indicating that PFDCHQ has better thermal stability during high-temperature stage in nitrogen atmosphere.

Fig. 2. TG and DTG curves of PFDCHQ in nitrogen (a) and air (b) atmosphere

TG-FTIR was usually used to analyze the gaseous products during the thermal degradation. The FTIR spectra of pyrolysis products of PFDCHQ at different temperatures are shown in Fig. 3. The relevant characteristic absorbing peaks appear at 3738 cm^{-1} (H_2O), 3015 cm^{-1} (Cp ring), 2360 cm^{-1} (CO_2) and 1508 cm^{-1} (aromatic compounds and Cp ring) [40, 41]. Before 250 °C, there is no obvious peak of CO_2 indicating that PFDCHQ has a good thermal stability. With the temperature increasing to 390 °C, the new absorbing peak at 3015 cm^{-1} (Cp ring) comes into sight [21], which is attributed to the decomposition of ferrocene-containing compounds at high temperature. New peaks of 1262 cm^{-1} and 1180 cm^{-1} at 400 °C can be attributed to P=O and C-O-C generated from DOPO-containing segments [42, 43]. When the temperature rises to 500 °C, the absorption intensity of P=O, C-O-C and aromatic compounds are weakened, and it can be inferred that the rest of P element and aromatic compounds remain in the condensed phase and take part in the formation of char residue [44].

Fig. 3. The TG-FTIR spectra of volatilized products at different temperatures during thermal decomposition of PDPFDE under N_2

To further identify the thermal degradation mechanism of PFDCHQ, Py-GC/MS test was performed. The total ion chromatogram and analysis data are shown in Fig. 4 and Table S1. The predominant decomposition volatiles of PFDCHQ are ethanol, phenol, 2-methoxyphenol, biphenylene, dibenzofuran, o-hydroxybiphenyl and fluorine, corresponding to the peaks 1, 2, 3, 6, 7, 8 and 9, respectively. Impressively, some aromatic compounds are produced, such as naphthalene (peak 4), fluorine (peak 9) and phenanthrene (peak 10).

Fig. 4. Total ion chromatogram of PFDCHQ

The pyrolysis mechanism of PFDCHQ can be further elucidated based on the cracking product in Py-GC/MS and shown in Scheme 3. With the increasing temperature, the O=C-O bond is firstly dissociated; decomposing into two parts of ferrocene-based group and DOPO-containing species. Subsequently, the groups on the two sides of ferrocene derivatives begin to cleave, producing CO₂ and ferrocene. Besides, the derivatives containing DOPO groups begin to decompose to produce 6-methyl-6H-dibenzo[c,e][1,2]oxaphosphinine 6-oxide (peak 11 in Fig. 4). It is possible to speculate that 6-methyl-6H-dibenzo[c,e][1,2]oxaphosphinine 6-oxide could release DOPO free radical, then proceed to generate PO₂ and PO radicals, accompanied by biphenylene and dibenzofurans, respectively [45, 46], since the biphenylene (peak 6) and dibenzofuran (peak 7) were detected in the chromatogram of PFDCHQ (Fig. 4). The PO₂ and PO radicals can contribute to flame inhibition by trapping active H and HO free radicals and stopping the chain reaction [47]. The analysis result of Py-GC/MS is consistent with the TG-FITR and TG data of PFDCHQ under nitrogen condition.

Scheme. 3. Possible pyrolytic route of PFDCHQ during thermal degradation

3.3. Thermal properties of EP/PFDCHQ composites

Thermogravimetric analysis is the most common method for evaluation of the thermal decomposition property of polymeric materials. Fig. 5 illustrates the TG and DTG curves of EP-0, EP-5 and EP-6 in nitrogen atmosphere. The onset degradation temperature (T_d) of samples is evaluated by the temperature at 5 wt% weight loss ($T_{-5\%}$) and the char residues at 700 °C are obtained from the TG curves; the temperature at maximum weight loss rate (T_{max}) of samples is obtained from the DTG curves. Some important data are listed in Table 2. The DTG curves of EP-0, EP-5 and EP-6 present one decomposition step with maximum mass loss rate at 368.2, 351.5 and 357.1 °C respectively. The $T_{-5\%}$ of EP-5 and EP-6 are lower than EP-0, which may be attributed to the fact that the introduction of ferrocene group can promote the advanced thermal degradation of epoxy resin [35], which would provide more carbon source to form protective char layer. Combining the self-high-charring properties of PFDCHQ, the resulting char residue of EP-5 (25.1 wt%) and EP-6 (22.1 wt%) are both higher than EP-0 (16.8 wt%) at 700 °C.

Table 2. TGA data of EP-0, EP-5 and EP-6

Samples	$T_{-5\%}$ (°C)	T_{max} (°C)	Char residues (700 °C) wt%
EP-0	319.3	368.2	16.8
EP-5	296.9	351.5	25.1
EP-6	283.1	357.1	22.1

Another important parameter for evaluating the thermal stability of epoxy resin is glass transition temperature (T_g). Thus DSC results of EP/PFDCHQ composites are shown in Fig. 6. The T_g value of

EP-0 is 122 °C and the T_g value of EP-5 increases to 131 °C with 5 wt% PFDCHQ loading. This may be attributed to the rigid structure (ferrocene unit and benzene ring) of PFDCHQ, which can limit the movement of epoxy resin molecular chain [48]. As the content of PFDCHQ reaches to 6 wt%, the T_g value of EP-6 decrease slightly due to the aggregation of excessive PFDCHQ.

Fig. 5. TG (a) and DTG (b) curves of EP-0, EP-5 and EP-6 in nitrogen

Fig. 6. DSC curves of EP-0, EP-5 and EP-6

3.4. Fire behavior and flame-retardancy

The limiting oxygen index (LOI) and UL-94 test are widely used to evaluate the flammability of materials. The LOI values and the experiment results of UL-94 are shown in Table 3. The EP-0 burns quickly after ignition in both LOI and UL-94 tests. When adding 5 wt% PFDCHQ, the LOI value of EP-5 can reach 32.0% and easily pass the V-0 rating. The real-time digital photos of some samples (EP-0, EP-3, EP-5 and EP-6) during UL-94 tests are shown in Fig. 7. After evacuating the source of fire, EP-0 continues to burn without a sign of extinguish, while EP-5 was extinguished naturally in 10 s, indicating that the incorporation of PFDCHQ do improve the fire retardancy for EP, which is attributing to the three reasons: 1) The PO and PO₂ radicals generated from DOPO

structure inhibit flame by trapping H and HO fragments; 2) The addition of PFDCHQ promote the initial catalytic charring action on the surface of EP-5 [49]; 3) it is notable that an obvious blowing-out effect can be observed for EP-5, which is very important to wipe the flame away rapidly in UL-94 testing [50-52]. However, the LOI values and UL-94 ratings of EP-6 and EP-7 decrease probably due to two reasons: 1) the aggregation of excessive PFDCHQ; 2) the more ferrocene groups should result in a faster degradation rate than the charring rate of EP composite during combustion. These results suggest that an appropriate loading amount of PFDCHQ is a key factor for the formation of suitable strong char layer to satisfy the demanded inner volatile gas pressure to blowing-out effect.

Fig. 7. The digital photos during vertical burning test of EP-0, EP-3, EP-5 and EP-6

Table 3. LOI and UL-94 data of EP and its composites

Samples	LOI (%)	UL-94			
		t ₁	t ₂	Rating	Dripping
EP-0	24.5 ± 0.3	> 40	-	NR	NO
EP-3	29.2 ± 0.2	13.6	5.3	V-1	NO
EP-4	30.6 ± 0.4	13.2	4.6	V-1	NO
EP-5	32.0 ± 0.3	4.0	3.1	V-0	NO
EP-6	30.9 ± 0.2	10.5	2.9	V-1	NO
EP-7	30.3 ± 0.3	11.6	4.2	V-1	NO

t₁ and t₂ are the extinguish time after two 10 second ignition; NR is no rating.

Cone calorimeter (CC) test is widely used to detect the combustion characteristic of the polymeric materials [53]. Fig. 8 showed the heat release rate (HRR), total heat release (THR), smoke production release (SPR) and mass curves of EP-0, EP-5 and EP-6. Other various important data obtained from measurements in cone calorimeter, such as the time-to-ignition (TTI), peak heat release rate (pHRR), time-to-pHRR (t-pHRR), average effective heat of combustion (AEHC), fire growth rate (FIGRA), average specific extinction area (ASEA) and the char residue yield, are

summarized in Table 4. The pHRR is one of the most important fire behavior parameters for fire retarding materials. In Fig. 8 (a, b), the pHRR of EP-5 and EP-6 reduced to 939.3 kW/m², 872.3 kW/m², meanwhile the THR decreased to 89.2 MJ/m² and 83.5 MJ/m² respectively when compared to EP-0. The reason is probably attributed to PO and PO₂ free radicals, produced by DOPO structure in PFDCHQ during combustion, which can interrupt the chain reaction by capturing H and HO fragments [44, 54, 55]. Unfortunately, the results of cone calorimetry test show lower fire retardancy efficiency compared to LOI and UL-94 data. What's more, the FIGRA of EP-5 8.2 kW/m²s is higher than that of EP-0 (6.9 kW/m²s). This may be due to the fact that the catalytic degradation effect of ferrocene is slightly stronger than the free radical quenching under continuously forced heating during cone calorimetry test. Fig. 8(c) shows the mass curves of EP-0, EP-5 and EP-6 composites. The higher char residue was obtained for EP-5, illustrating that the char layer is produced by EP-5 during burning. Furthermore, it is worth noting from the mass curves that EP-5 and EP-6 begin to decompose earlier than EP-0 due to the catalytic degradation effect of PFDCHQ. The smoke production release (SPR) of EP-0, EP-5 and EP-6 are shown in Fig. 8(d). It is found that the SPR of EP-5 decreases a lot compared to EP-0, suggesting that PFDCHQ could inhibit the production of smoke for epoxy resin to a certain extent.

Fig. 8. (a) HRR, (b) THR, (c) Mass loss and (d) SPR curves of EP-0, EP-5 and EP-6 from cone calorimeter tests

Table 4. Detailed CC data of EP-0, EP-5 and EP-6

Samples	TTI (s)	t-pHRR (s)	pHRR (kW/m ²)	THR (MJ/m ²)	AEHC (MJ/kg)	ASEA (m ² /kg)	Residue (wt%)
EP-0	63± 13	170 ± 9	1146.1 ± 16.1	99.4 ± 0.4	24.71 ± 0.19	695.87 ± 9.37	10.2 ± 1.4
EP-5	61 ± 4	114 ± 4	939.3 ± 59.9	89.2 ± 2.3	22.63 ± 0.48	588.67± 17.07	15.8 ± 1.0
EP-6	56 ± 9	113 ± 4	872.3 ± 26.0	83.5 ± 4.1	21.69 ± 1.23	623.94 ± 21.16	14.9 ± 0.8

The CO₂ and CO product rate curves of EP-0, EP-5 and EP-6 are shown in Fig. 9. From Fig. 9, it can be seen that the CO₂ release rate of EP-5 and EP-6 are much lower than EP-0, while their CO production rate are higher than EP-0. The result indicates that the EP/PFDCHQ composites cannot be fully burned due to the existence of PO and PO₂ radicals released by PFDCHQ, which play a distinct fire retardant role in gas phase.

Fig. 9. CO₂ (a) and CO (b) release rate curves of EP-0, EP-5 and EP-6 from cone calorimeter tests

From Table 4, it can be found that the EP-5 and EP-6 show a slight reduction in TTI and t-pHRR, which may be assigned to the catalysis degradation effect of ferrocene group in PFDCHQ. With respect to the AEHC, when adding 5 wt%, the AEHC shows a slight decrease from 24.71 (EP-0) to 22.63 MJ/kg. The ASEA is used to measure the ability of the material to produce smoke. The ASEA value of EP-5 is 588.67 m²/kg, which is lower than that of EP-0 (695.87 m²/kg) indicating that PFDCHQ not only can improve the flame retardancy, but also can suppress the smoke-production of EP.

3.5. Flame retardant mechanism in both condensed and gas phases

The flame retardant mechanism of EP/PFDCHQ composites was analyzed by the condensed and gas-phase analysis. FTIR spectra of pyrolysis products of EP-0 and EP-5 composites at different temperatures were recorded during TG-FTIR test and are shown in Fig. 10. The main thermal decomposition products of EP-0 can be clearly seen, such as H₂O (3600-4000 cm⁻¹), CO₂ (2307-2380 cm⁻¹), aromatic compounds (3010-3030, 1512, 825, 742 cm⁻¹) and hydrocarbons (2800-3100 cm⁻¹ and 1100-1250 cm⁻¹) [56-58]. For EP-5, The new absorption bands at 1262 cm⁻¹ and 1180 cm⁻¹ belong to the P=O and C-O-C structures, respectively. In addition, there are no significant peaks of hydrocarbon for EP-5, indicating lower the smoke-production during combustion. It is also worth noting that the peaks of aromatic compounds (825 cm⁻¹ and 742 cm⁻¹) for EP-5

(Fig.10(b2)) disappeared, but the peak around 1512 cm^{-1} remains stronger than that of EP-0, which can be attributed to the aromatic compounds originated from PFDCHQ. This result is consistent with the TG-FTIR (Fig.3) of PFDCHQ.

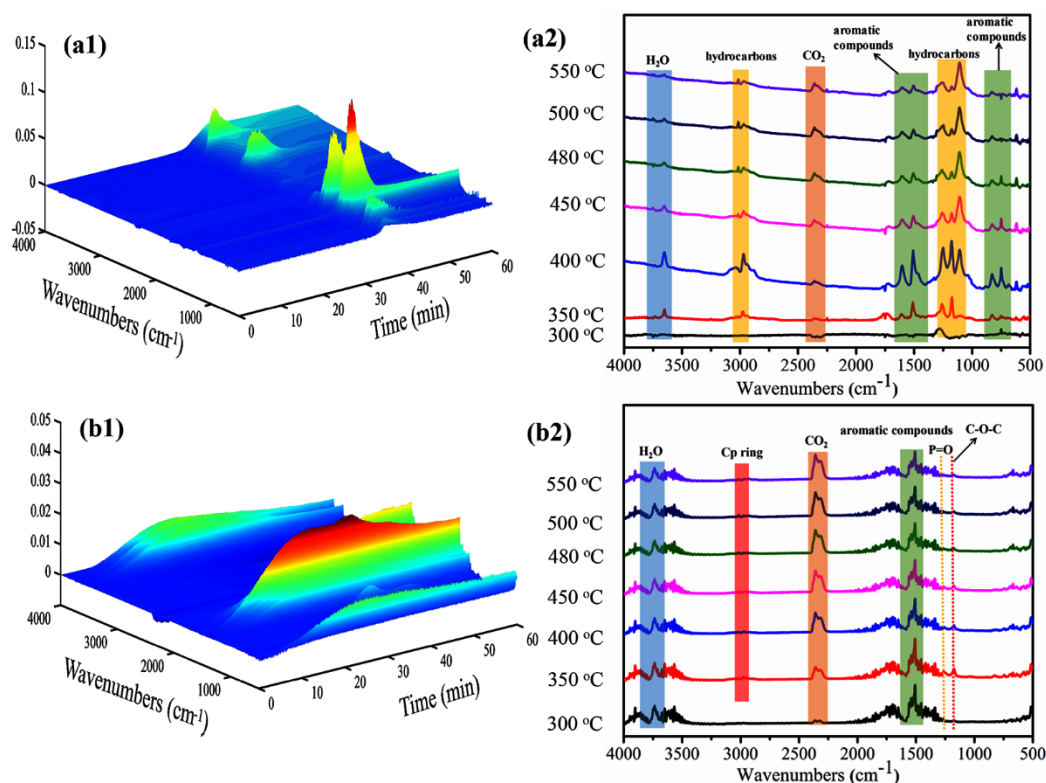

Fig. 10. 3D FTIR and FTIR spectra of the pyrolysis products of EP-0 (a1,a2) and EP-5 (b1,b2) at different temperature

In order to further understand the change of the pyrolysis products, total and some specific products of EP-0 and EP-5 are revealed in Fig. 11. It can be seen that the total pyrolysis products for EP-5 are lower than EP-0 (Fig. 11(a)) indicated that PFDCHQ can prevent epoxy resin from further combustion. Furthermore, Fig. 11(b, c, and d) display the absorbance intensity of CO_2 , hydrocarbons, and aromatic compounds. Hydrocarbons and aromatic compounds belong to flammable gases and tend to aggregate into smoke particles, which increase the probability of fire accident [59]. Fortunately, the absorbance intensity of hydrocarbons and aromatic compounds from EP-5 are much lower than EP-0, implying that more of them had remained in condensed phase to form the compact protective char layer [60]. Moreover, the production of CO_2 from EP-5 is higher than EP-0 and it helps to dilute flammable gases, thereby preventing further combustion of the matrix materials.

Raman spectroscopy, a powerful tool for the characterization of carbonaceous materials, has been applied to analyze the char residues of EP composites. Fig. 12 shows the Raman spectra of EP-0 and EP-5. The degree of graphic structure is evaluated by the ratio of I_D/I_G , where I_D and I_G are the integrated intensities of D ($\sim 1360 \text{ cm}^{-1}$) and G ($\sim 1590 \text{ cm}^{-1}$) bands [61], respectively. Generally speaking, the lower ratio of I_D/I_G means the higher graphitization degree of char [62]. And the higher graphitized char can effectively retard the flame and protect the inner polymer

matrix from further burning. The values of I_D/I_G follow the sequence of EP-0 (1.589) > EP-5 (1.137), illustrating that the addition of PFDCHQ can contribute to form a stable graphic structure char layer.

Fig. 11. Absorbance of pyrolysis products for EP-0 and EP-5 versus temperature: (a) gram-schmidt, (b) CO_2 , (c) hydrocarbons and (d) aromatic compounds

Fig. 12. Raman spectra of char residues of EP-0 and EP-5 composites after UL-94 tests

To further clarify the structure of the fire-resistant barrier on the surface, the char residues of EP-0 and EP-5 after UL-94 tests were analyzed after UL-94 tests using FTIR and shown in Fig. 13. It is obvious that the two spectra are different between EP-0 and EP-5. The weak peak at around 1360

cm^{-1} of EP-5 is due to the stretching vibration of $\text{P}=\text{O}$ [63]. Meanwhile, the new absorption peak of EP-5 appearing at 885 cm^{-1} is assigned to the stretching vibrations of $\text{P}-\text{O}-\text{P}$ or $\text{P}-\text{O}-\text{Ph}$ bonds [64, 65]. These bonds can play a role of cross-linker to link different aromatic species and strengthen carbon layers [66, 67]. The new peak at 753 cm^{-1} should belong to C-H deformation vibrations of aromatic ring.

Fig. 13. FTIR spectra of the char residues of EP-0 and EP-5 composites after UL-94 tests

The morphology of the char residues after UL-94 tests was investigated by SEM. Fig. 14(a, b, c, and d) display the morphologies of char residues from EP-0, EP-3, EP-5 and EP-6, respectively. The residue of the EP-0 shows a loose and fluffy structure. This type of carbon layer is not conducive to prevent the transmission of combustible gases and heat. The introduction of PFDCHQ in EP matrix leads to more char residues, especially for EP-5, which effectively protects the internal epoxy resin matrix when the fire contacts them. But, an important phenomenon must be emphasized: all the char residues of EP composites are not continuous and compact, which may be helpful to the abrupt release of volatile gas, generating blowing-out effect to kill flame.

Based on the analysis above, we can attempt to explain the incoherence between LOI and UL-94 and CONE tests; namely, why the pHRR value decrease slightly in contrast to the excellent LOI and UL-94 performance for EP-5. Firstly, the PO and PO_2 free radicals will come into play in the early stage after ignition to inhibit the fast combustion of EP matrix, which should facilitate the formation of char layer, as can be seen in UL-94 test (Fig. 14). Secondly, a suitable compact char layer produced in UL-94 test is definitely crucial to match initial blowing-out effect for killing flame rapidly (EP-5). Less or rich char layer is not conducive to generate blowing-out effect, indicating that a proper loading of PFDCHQ is necessary and critical. However, under the continuous irradiation in the CONE test, in spite of existing radical trapping effect in gas phase, the ferrocene mainly play an catalyzing degradation role on EP matrix, resulting in no sufficient char layer to prevent further combustion of EP matrix, then a high pHRR value appears for EP-5. Actually, more investigations are needed to elucidate profoundly the fire retardancy mechanism

of EP/PFDCHQ system in the future.

Fig. 14. Different magnifications of SEM micrographs of EP-0 (a1-a3), EP-3 (b1-b3), EP-5 (c1-c3) and EP-6 (d1-d3) after UL-94 tests

3.6. Mechanical properties

Mechanical property is the important factor to value the practical usability of composites. Impact strength, tensile strength, elongation at break and Young's modulus values of various EP/PFDCHQ composites are shown in Fig. 15 and Table S2. With the increasing PFDCHQ amount, the impact strength of EP/PFDCHQ composites tends to increase firstly and then decrease, and the Young's modulus is always higher than EP-0. The results could be explained by the introduction of rigid groups (ferrocene and benzene ring) into EP matrix. Compared to EP-0, the tensile strength and elongation at break of EP/PFDCHQ composites are both decreased a lot caused by the formation of internal stress during curing of EP [68]. The internal stress could create micro-cracks and voids to reduce the mechanical properties of materials. On the other hand, the excessive PFDCHQ is not uniformly distributed in the EP matrix, which causes the PFDCHQ acts as stress concentrators and decreases the mechanical properties of EP.

The SEM micrographs of EP-5 and EP-7 composites are shown in Fig.16. The fractured surface of EP-5 is smooth, while the cross-sectional morphology of EP-7 has many textures and is much

rougher compared to EP-5, attributing to the agglomeration of excess PFDCHQ in epoxy resin matrix, thereby the agminated PFDCHQ may act as the stress concentration point to reduce the mechanical properties of EP/PFDCHQ composites.

Fig. 15. The impact strength, tensile strength, elongation at break and Young's modulus of pure EP and EP/PFDCHQ composites

Fig. 16. SEM micrographs of the fractured surface of EP-5 (a) and EP-7 (b) composites

4. Conclusion

In this article, a novel DOPO and ferrocene-based oligomer (PFDCHQ) was first successfully synthesized and used as flame retardant in epoxy resin. The TGA results show that the PFDCHQ can contribute improved thermal and thermo-oxidative stability at high temperature region as well as char yield to epoxy resin matrix. The flame retardance and combustion behavior of EP-0 and EP-5 were comprehensively investigated. With 5 wt% addition of PFDCHQ, the LOI value of EP-5 is increased to 32.0% and can pass the V-0 rating. But it is unfortunate that the data of cone calorimeter test is not very well. The PFDCHQ can catalyze epoxy resin to form highly graphitization aromatic char in condensed phase and improve the char residue; PFDCHQ produces PO and PO₂ fragments in gaseous phase for inhibiting flame development; moreover, an obvious blowing-out effect can be observed in UL-94 test for EP-3 and EP-5. This research provides a new idea for the molecular design of phosphorus and ferrocene-containing flame retardant system.
