30 **Peak running speeds in professional male football: influence of division and playing**

31 **position**

32

**33 Abstract**

34 Well established physical demands of competitive professional football facilitate prescription  
35 and monitoring of training. However, many factors influence these physical demands with  
36 implications for efficacious practice. Match-play data were analyzed over two seasons using  
37 global positioning systems technology, differentiating English Championship (33 matches) and  
38 League One (27 matches) demands. Playing position categorized wide and central defenders  
39 and midfielders, and forwards. Peak running speeds defined the outcome measure, assessing  
40 the influence of competition level and playing position across 1, 5 and 10-minute rolling  
41 average durations using a linear mixed model. Significant effects were detected for competition  
42 level ( $F_{1,324.5} = 5.44, P = 0.02$ ) and playing position ( $F_{4,328.3} = 89.90, P < 0.001$ ). League One  
43 matches demonstrated greater peak running speeds than Championship matches (mean  
44 difference =  $2.72 \text{ m}\cdot\text{min}^{-1}$  [95%CI: 0.4, 5.0]). No difference was observed between central and  
45 wide midfielders (mean difference =  $0.62 \text{ m}\cdot\text{min}^{-1}$  [95%CI: -3.1, 4.3]). Wide midfielders  
46 presented faster peak running speeds than forwards (mean difference =  $18 \text{ m}\cdot\text{min}^{-1}$   
47 [95%CI:14.1, 22.1],  $P < 0.05$ ), central defenders (mean difference =  $25 \text{ m}\cdot\text{min}^{-1}$  [95%CI: 21.7,  
48 29.8],  $P < 0.05$ ) and wide defenders (mean difference =  $12 \text{ m}\cdot\text{min}^{-1}$  [95%CI: 8.2, 16.5],  $P <$   
49  $0.05$ ). Interaction effects were found for division\*position ( $F_{4,328.3} = 2.57, P = 0.038$ )  
50 demonstrating greater running speeds in League One, except for central defenders. Wide  
51 midfielders presented greater peak 1-minute running speeds, whereas 5 and 10-minute peak  
52 running speeds were greatest in central midfielders. The sensitivity of peak running speeds to  
53 competition level and playing position have implications for training prescription, monitoring  
54 particularly when transitioning between competition levels, determining and monitoring  
55 positional training intensities, and objective targets for progressive overload during  
56 rehabilitation.

59 monitoring

60

## 61 INTRODUCTION

62 Time motion analysis, and more recently, global positioning systems (GPS) have become  
63 effective tools for quantifying movement demands during professional association football  
64 matches and monitoring physical training (8,13, 17,44). Activity profiles of out-field players  
65 have shown players to cover between 9-12 km during a competitive match (3, 38), representing  
66 speeds between 100-133 m·min<sup>-1</sup> across a 90-minute match. Despite the physical demands of  
67 professional association football being well established, coaches and practitioners face the  
68 challenge of designing specific training programs that best replicate match-play. Traditionally  
69 absolute running demands from matches have been used to monitor training intensities (24, 15)  
70 but coaches and practitioners are advised to avoid a ‘one-size-fits-all’ approach in order to  
71 maximize training efficiency whilst targeting individual needs (21, 37).

72

73 One of the factors influencing running demands is playing standard (33, 38, 44, 27) and  
74 analyses of movement demands across different playing standards have made strong  
75 associations to the amount of high-intensity running distance and, by association, match  
76 intensity (27, 28, 33). Morgans et al. (35) reported greater total distance covered during an  
77 English Premier League season compared with the preceding season in the English  
78 Championship, but concluded that total distance provides relatively little practical value in  
79 relation to physical preparation and match recovery. English Championship and League One  
80 players have demonstrated greater total distances, and distance at higher velocities than Premier  
81 League players (12, 20), therefore suggesting that high intensity running might have more  
82 specific value in training prescription and injury risk. Another factor influencing running

83 demands is playing position (3, 41) which has been observed to influence total (7, 9, 26) and  
84 high-speed distance covered (10, 26, 36). Such factors are important when considering the  
85 individualization of training prescription (21, 37).

86

87 The temporal pattern of high intensity running during match-play can be influenced by a  
88 number of factors including pacing (22), different match scenarios (9, 14), and fatigue (6).

89 Early notational analyses highlighted reductions in high-intensity running in the second half of  
90 match-play (2, 33), but contemporary developments facilitate the investigation of within-match

91 fluctuations using predefined time periods, often using 5-minute or 15-minute periods (4, 5, 9,

92 11, 34, 42, 44). However, the use of these pre-defined time periods may lack sensitivity to

93 detect small fluctuations in running intensity as the most intense period of a match may not fall

94 exactly into these pre-defined periods (20). The rolling average technique has been used to

95 quantify peak running demands ranging from 1-minute to 10-minute periods (16, 17, 18, 23,

96 43, 44), with pre-defined time periods demonstrating a 20-25% underestimation of peak high

97 velocity running distance compared to rolling averages (43). For the practitioner, the

98 implications of such an underestimation in match-demands would have further implications for

99 physical preparation and injury risk (25). The aim of this study was to investigate the

100 sensitivity of competition level and playing position on the peak running speeds during

101 professional association football, with implications for training prescription and monitoring.

102 To acknowledge the confounding issues in playing position and standard, analysis was

103 extended to compare data from both English Championship League and English League One

104 seasons within the same club.

105

## 106 **METHODS**

### 107 **EXPERIMENTAL APPROACH TO THE PROBLEM**

108 Data were collected on all outfield players during 2017-18 English Championship ( $n = 33$ , 8  
109 wins, 8 draws, 17 losses) and 2019-20 English League One seasons ( $n = 27$ , 5 wins, 9 draws, 13  
110 losses) using 10Hz GPS units (Catapult Sports™, OptimEye S5, Firmware 7.4, Leeds, United  
111 Kingdom). Only league matches were included in the study design in order to negate the  
112 perceived relative importance of knock-out competitions and to maintain the standard of the  
113 opposition. The team utilized a 4-2-3-1 formation aiming to play a medium block pressing  
114 style. Players were categorized into the following playing positions: central defender (C.Def,  
115  $n = 9$ ), wide defender (W.Def,  $n = 8$ ), central midfielder (C.Mid,  $n = 18$ ), wide midfielder  
116 (W.Mid,  $n = 7$ ), or forwards ( $n = 10$ ), with technical formation consistent across both seasons.

117

## 118 SUBJECTS

119 Fifty-seven male outfield professional association football players ( $25.9 \pm 5.2$  years [range  
120  $18.2-37.7$  years],  $1.8 \pm 0.0$ m,  $79.4 \pm 8.6$ kg) participated in the study. All subjects had been  
121 training in a soccer club environment for two years or more prior to the study. Between  
122 matches, outfield players completed a consistent training structure (3-4 football-based sessions  
123 and 2 gym-based sessions) unless a mid-week fixture was scheduled (2-3 football-based  
124 sessions and 1 gym-based sessions). Data were collected as part of routine monitoring and  
125 testing carried by the club's medical personnel with written permission provided by the club  
126 and players, outlined within their contractual agreements. Study approval was granted from  
127 the club and host university ethics committee for the use of anonymised retrospective data. All  
128 participants provided written and verbal informed consent in accordance with department and  
129 faculty research ethics committees at the host university, and in accordance with the 2013  
130 Helsinki Declaration.

131

132

## 133 PROCEDURES

134 Data collection took place during the competitive seasons of 2017-18 and 2019-20. Prior to the  
135 competitive season, all subjects completed a pre-season training period consisting of technical  
136 football, aerobic conditioning and gym-based sessions in order to ensure an appropriate level  
137 of fitness. Prior to each match, all subjects underwent a consistent team based warm up  
138 including mobility, co-ordination, sprint, technical, possession and position-specific exercises.  
139 During each match, all subjects wore a GPS located between scapula in a custom-made vest  
140 underneath their playing shirt. Following each match, data was downloaded (Catapult  
141 Sports™, Openfield Software, version 2.3.3) and preliminary analyzed to delimit playing time  
142 for each player. Each data set was screened for satellite coverage and horizontal dilution of  
143 precision (HDOP) using an inclusion criterion of  $>6$  satellites and  $\leq 1.0$  respectively, which are  
144 in accordance to previous guidelines for acceptable GPS coverage (32). Raw speed data files  
145 were exported and further analyzed using a customized software (R, v1.2.503) which removed  
146 data points with speed  $\geq 10 \text{ m}\cdot\text{s}^{-1}$  and/or accelerations  $\geq \pm 6 \text{ m}\cdot\text{s}^{-2}$ . A total number of 2058  
147 observations were recorded for analysis across both seasons (2017-18 season  $n = 1191$ , 2019-  
148 20 season  $n = 867$ ; C.Def  $n = 396$ , W.Def  $n = 333$ , C.Mid  $n = 600$ , W.Mid  $n = 321$ , Forwards  
149  $n = 408$ ).

150

## 151 STATISTICAL ANALYSES

152 The dependent variable was defined as the peak average running speed, quantified as distance  
153 per minute sustained during match-play, calculated using the rolling average technique (17, 18)  
154 with durations of 1-minute, 5-minutes and 10-minutes, similar to those previously reported (16,  
155 17, 43, 44), by playing position, and division. A Linear Mixed Model (LMM) was performed  
156 to test for the effects of competition level and playing position on average peak running speed,  
157 and interactions between competition level and position. Within the mixed-model framework

158 both fixed-factors and random-factors can be modelled. While systematic variability between  
159 conditions for fixed factors is explicitly estimated, the variability of random factors is used to:  
160 (1) estimate the extent to which mean responses vary across units of the random factor; (2)  
161 allow inferences about whether fixed effects generalize beyond the units sampled in the random  
162 factor; and (3) remove variability in responses that are associated with the random factor rather  
163 than the conditions of experimental interest (i.e, reduce Type I error rate) (31). In the LMM  
164 peak running speed was entered as the dependent variable. The variables: duration (i.e. 1-  
165 minute, 5-minute, and 10-minute), competition level (i.e. League 1 and Championship) and  
166 playing position were entered in the model as fixed factors along with the interaction terms,  
167 division\*position and duration\*position. Participant was entered into the model as a random  
168 factor. Post-hoc pairwise comparisons were performed to test for differences in grouping  
169 conditions for duration, division and position. All statistical analyses were performed using a  
170 specialist software (IBM SPSS Statistics 20, Chicago, IL, USA). Data are presented as mean  
171 difference, 95% confidence intervals, and an alpha level of 0.05 was used to determine  
172 statistical significance.

173

## 174 **RESULTS**

175 Figures 1-3 summarizes the influence of rolling average duration on peak running speeds by  
176 playing position and competition level.

177

178 **\*\* Insert Figures 1-3 near here \*\***

179

180 Results from the LMM showed a significant effect for competition level ( $F_{1,324.5} = 5.439$ ,  $P =$   
181  $0.02$ ) and playing position ( $F_{4,328.3} = 89.897$ ,  $P < 0.001$ ). Pairwise comparisons revealed that

182 matches in League One elicited a peak speed of  $2.7 \text{ m}\cdot\text{min}^{-1}$  faster than those in the  
183 Championship (mean difference =  $2.7 \text{ m}\cdot\text{min}^{-1}$ , 95%CI: 0.43, 5.02,  $P = 0.02$ ).

184

185 Pairwise comparisons revealed significant differences between all positions ( $P < 0.05$ ) except  
186 C.Mid and W.Mid where no significant difference was observed (mean difference =  $0.6 \text{ m}\cdot\text{min}^{-1}$   
187 95%CI: -3.09, 4.32). Central midfielders and W.Mid presented with the fastest peak running  
188 speeds, running faster than W.Def, C.Def and Forwards. Specifically, C.Mid ran faster than  
189 W.Def (mean difference =  $13.0 \text{ m}\cdot\text{min}^{-1}$ , 95%CI: 9.82,16.27,  $P < 0.001$ ), C.Def (mean  
190 difference =  $26.4 \text{ m}\cdot\text{min}^{-1}$ , 95%CI: 23.25, 29.53,  $P < 0.001$ ), and Forwards (mean difference =  
191  $18.6 \text{ m}\cdot\text{min}^{-1}$ , 95%CI: 15.67, 21.83,  $P < 0.001$ ). Wide midfielders ran faster than W.Def (mean  
192 difference =  $12.4 \text{ m}\cdot\text{min}^{-1}$ , 95%CI: 8.28, 16.57,  $P < 0.001$ ), C.Def (mean difference =  $25.8$   
193  $\text{m}\cdot\text{min}^{-1}$ , 95%CI: 21.7,29,  $P < 0.001$ ), and Forwards (mean difference =  $18.1 \text{ m}\cdot\text{min}^{-1}$ , 95%CI:  
194 14.11,22.16,  $P < 0.001$ ). Wide defenders ran faster than both C.Def (mean difference = 13  
195  $\text{m}\cdot\text{min}^{-1}$ , 95%CI: 9.7,16.99,  $P < 0.001$ ) and Forwards (mean difference =  $5.7 \text{ m}\cdot\text{min}^{-1}$ , 95%CI:  
196 2.12,9.3,  $P = 0.002$ ), while Forwards ran faster than C.Def (mean difference =  $7.6 \text{ m}\cdot\text{min}^{-1}$ ,  
197 95%CI: 4.12,11.15,  $P < 0.001$ ).

198

199 The LMM also revealed significant results for the interaction term division\*position ( $F_{4,328.3}$   
200 =2.573,  $P = 0.038$ ). Matches in League One were faster than those in the Championship when  
201 playing as W.Def ( $142.0$  vs.  $138.4 \text{ m}\cdot\text{min}^{-1}$ ), C.Mid ( $153.5$  vs.  $153.0 \text{ m}\cdot\text{min}^{-1}$ ) and W.Mid  
202 ( $157.9$  vs.  $147.4 \text{ m}\cdot\text{min}^{-1}$ ). Only a marginal difference was observed between League One and  
203 Championship for the Forwards position ( $135$  vs.  $134 \text{ m}\cdot\text{min}^{-1}$ ), while matches in the  
204 Championship were faster than League One for C.Def (i.e.  $127$  vs.  $126 \text{ m}\cdot\text{min}^{-1}$ ).

205

## 206 **DISCUSSION**

207

208 The aim of the current study was to quantify peak running speeds during professional football  
209 association match-play whilst acknowledging the influence of competition level and playing  
210 position, with implications for the practitioner in exercise prescription and monitoring.

211

212 Our findings show that League One matches elicit greater peak running speeds Championship  
213 matches, with similar magnitudes to those reported between professional and semi-professional  
214 rugby league players (27). Peak running speeds were  $2.7 \text{ m} \cdot \text{min}^{-1}$  higher in League One which  
215 is equivalent to 0.2 kilometres per hour. This may be of little practical significance, suggesting  
216 that no fundamental changes are required for a club or player transitioning between these  
217 divisions. The current study failed to determine the frequency to which players are exposed to  
218 these peak running speeds, which may be an important when comparing differences between  
219 competition levels. Bradley et al, (12) reported greater speeds in League One players compared  
220 to Championship and Premier League players. However, technical indicators were superior in  
221 higher competition standards. A recent study demonstrated greater peak running speeds during  
222 negative transitions in comparison to positive transitions, counter attacks and high pressing (9).  
223 This may explain the current findings, as potentially greater technical indicators may exist in  
224 the Championship, suggesting that players in competing in League One may require to  
225 physically exert themselves more as a consequence to turnovers in possession and end to end  
226 activity.

227

228 Despite trivial differences between competition levels, peak running speeds reported here were  
229 higher than average running demands ( $100\text{-}133 \text{ m} \cdot \text{min}^{-1}$ ) reported over 90-minutes across  
230 various domestic leagues (41). The context of these findings is important providing an  
231 appropriate guide for practitioners to prescribe and monitor football-specific drills, for example

232 peak running speeds can be used to determine progressive intensities during possession drills  
233 and small sided games to physically prepare players for the level of competition, but are not  
234 advised as a guide for traditional conditioning. It should also be acknowledged that differences  
235 in running performance may be of little practical concern given the potential influence of  
236 technical and tactical factors on running performance (35). Future research may wish to  
237 consider the relationships between technical and tactical factors on peak running speeds at  
238 different competition levels.

239

240 Differences in peak running speeds showed the following descending order: central  
241 midfielders, wide midfielders, wide defenders, forwards, central defenders. In the current  
242 study, positional differences in peak running speeds were reported across all playing positions  
243 except between central and wide midfielders. Our findings are similar positional trends to  
244 Delaney et al, (18) with lower peak running speeds in central defenders compared to all other  
245 positions. Although peak 1-minute running speeds in the current study were lower than  
246 Delaney et al, (18), peak 5-minute running speeds were similar. However, these findings  
247 represent senior teams from different domestic leagues and competition levels and are likely to  
248 demonstrate different technical and tactical factors which appear to influence physical output  
249 during match-play (12). In the current study, peak 1-minute running speeds were greatest in  
250 wide midfielders, however central midfielders elicited greater peak running speeds for 5-  
251 minute and 10-minute rolling average durations. This may reflect the technical and tactical  
252 responsibilities of these positions as central midfielders tend to cover more total distance across  
253 90-minutes, whereas wide players cover greater distances at higher speeds, working in shorter  
254 bouts (9, 10, 26, 36). The differences between playing positions have implications for training  
255 prescription and personalized monitoring and do not support the use of 'unit-specific' training  
256 classifying defenders, midfielders, forwards for example.

257

258 Significant interaction effects were found between competition level and playing position.  
259 League One matches elicited greater running speeds for wide defenders, central midfielders,  
260 wide midfielders and forwards compared to Championship matches, whereas Championship  
261 matches elicit greater running speeds for central defenders. These findings may be the result of  
262 superior technical factors at higher competition levels (12, 35); however, this was not  
263 established in the current study. Despite significant interactions being detected, differences in  
264 peak running speeds for central and wide midfielders across competition levels ranged from 1-  
265 10  $\text{m}\cdot\text{min}^{-1}$ , which is of little practical significance. Future research and practitioners should  
266 consider the frequency of exposure to peak running speeds across different competition levels  
267 in order to prescribe the appropriate volumes of high-intensity training. No significant result  
268 was found between competition level and all rolling average durations, with matches in League  
269 One being faster than those in the Championship.

270

271 Whilst there are clear practical implications in terms of objective prescription and monitoring  
272 of position-specific training, caution should be taken when generalizing beyond the specific  
273 sample and performance metrics used in the current study. Results from the current study  
274 should be applied to football-specific tasks rather than traditional conditioning practices.  
275 Practitioners should also consider the influence of technical and tactical factors on peak running  
276 speeds during match-play. Similarly, the positional classification used in the current study  
277 reflects the technical formation used by the club across these two seasons. These two seasons  
278 reflect an opportunity to compare two (of four) divisions within the same domestic structure,  
279 but changes in playing and non-playing staff etc. must be acknowledged. The dependent  
280 variable in the current study was defined as peak speed, expressed as meters per minute,  
281 enabling standardization across competition level and playing position. But additional metrics

282 warrant attention, including high-speed running, sprinting, acceleration and Playerload, in  
283 order to better evaluate peak demands and intermittent nature of match-play. Peak 1-minute  
284 running speeds in the current study represent a running speed of ~3.5 meters per second, well  
285 below the peak running speeds and maximal aerobic speeds observed in professional  
286 association football players (45). This reflects the intermittent nature of match-play where  
287 sprints are of relatively short distance and therefore duration, interspersed with active recovery  
288 and representing clusters of high intensity efforts. The detail of high intensity activities which  
289 comprise the peak demands per minute are worthy of attention, particularly given the  
290 association with injury mechanisms.

291

## 292 PRACTICAL APPLICATIONS

293 Peak running speeds appear to have little difference when comparing competition level,  
294 however positional differences are more apparent. Data from the current study supports the  
295 notion of position-specific prescription and monitoring of training based on peak running  
296 speeds during match-play, omitting a one-size fits all approach. As expected, peak running  
297 speeds decline within rolling average duration. Practitioners may therefore develop position-  
298 specific targets for football-specific training exercises to better prepare and monitor players for  
299 the more intense periods of match-play. This may also have implications for training design  
300 during end-stage rehabilitation and return to play.
