August 2008
How to obtain copies of this and other HTA Programme reports.

An electronic version of this publication, in Adobe Acrobat format, is available for downloading free of charge for personal use from the HTA website (http://www.hta.ac.uk). A fully searchable CD-ROM is also available (see below).

Printed copies of HTA monographs cost £20 each (post and packing free in the UK) to both public and private sector purchasers from our Despatch Agents.

Non-UK purchasers will have to pay a small fee for post and packing. For European countries the cost is £2 per monograph and for the rest of the world £3 per monograph.

You can order HTA monographs from our Despatch Agents:

– fax (with credit card or official purchase order)
– post (with credit card or official purchase order or cheque)
– phone during office hours (credit card only).

Additionally the HTA website allows you either to pay securely by credit card or to print out your order and then post or fax it.

Contact details are as follows:

HTA Despatch
 c/o Direct Mail Works Ltd
 4 Oakwood Business Centre
 Downley, HAVANT PO9 2NP , UK
 Email: orders@hta.ac.uk
 Tel: 02392 492 000
 Fax: 02392 478 555
 Fax from outside the UK: +44 2392 478 555

NHS libraries can subscribe free of charge. Public libraries can subscribe at a very reduced cost of £100 for each volume (normally comprising 30–40 titles). The commercial subscription rate is £300 per volume. Please see our website for details. Subscriptions can only be purchased for the current or forthcoming volume.

Payment methods

Paying by cheque
If you pay by cheque, the cheque must be in pounds sterling, made payable to Direct Mail Works Ltd and drawn on a bank with a UK address.

Paying by credit card
The following cards are accepted by phone, fax, post or via the website ordering pages: Delta, Eurocard, Mastercard, Solo, Switch and Visa. We advise against sending credit card details in a plain email.

Paying by official purchase order
You can post or fax these, but they must be from public bodies (i.e. NHS or universities) within the UK. We cannot at present accept purchase orders from commercial companies or from outside the UK.

How do I get a copy of HTA on CD?

Please use the form on the HTA website (www.hta.ac.uk/htacd.htm). Or contact Direct Mail Works (see contact details above) by email, post, fax or phone. HTA on CD is currently free of charge worldwide.

The website also provides information about the HTA Programme and lists the membership of the various committees.

This report should be referenced as follows:

Health Technology Assessment is indexed and abstracted in Index Medicus/MEDLINE, Excerpta Medica/EMBASE and Science Citation Index Expanded (SciSearch\textsuperscript{®}) and Current Contents\textsuperscript{®}/Clinical Medicine.
The Health Technology Assessment (HTA) Programme, part of the National Institute for Health Research (NIHR), was set up in 1993. It produces high-quality research information on the effectiveness, costs and broader impact of health technologies for those who use, manage and provide care in the NHS. ‘Health technologies’ are broadly defined as all interventions used to promote health, prevent and treat disease, and improve rehabilitation and long-term care.

The research findings from the HTA Programme directly influence decision-making bodies such as the National Institute for Health and Clinical Excellence (NICE) and the National Screening Committee (NSC). HTA findings also help to improve the quality of clinical practice in the NHS indirectly in that they form a key component of the ‘National Knowledge Service’.

The HTA Programme is needs-led in that it fills gaps in the evidence needed by the NHS. There are three routes to the start of projects.

First is the commissioned route. Suggestions for research are actively sought from people working in the NHS, the public and consumer groups and professional bodies such as royal colleges and NHS trusts. These suggestions are carefully prioritised by panels of independent experts (including NHS service users). The HTA Programme then commissions the research by competitive tender.

Secondly, the HTA Programme provides grants for clinical trials for researchers who identify research questions. These are assessed for importance to patients and the NHS, and scientific rigour.

Thirdly, through its Technology Assessment Report (TAR) call-off contract, the HTA Programme commissions bespoke reports, principally for NICE, but also for other policy-makers. TARs bring together evidence on the value of specific technologies.

Some HTA research projects, including TARs, may take only months, others need several years. They can cost from as little as £40,000 to over £1 million, and may involve synthesising existing evidence, undertaking a trial, or other research collecting new data to answer a research problem.

The final reports from HTA projects are peer-reviewed by a number of independent expert referees before publication in the widely read journal series *Health Technology Assessment*.

Criteria for inclusion in the HTA journal series

Reports are published in the HTA journal series if (1) they have resulted from work for the HTA Programme, and (2) they are of a sufficiently high scientific quality as assessed by the referees and editors.

Reviews in *Health Technology Assessment* are termed ‘systematic’ when the account of the search, appraisal and synthesis methods (to minimise biases and random errors) would, in theory, permit the replication of the review by others.

The research reported in this issue of the journal was commissioned by the HTA Programme as project number 05/17/04. The contractual start date was in November 2005. The draft report began editorial review in February 2007 and was accepted for publication in February 2008. As the funder, by devising a commissioning brief, the HTA Programme specified the research question and study design. The authors have been wholly responsible for all data collection, analysis and interpretation, and for writing up their work. The HTA editors and publisher have tried to ensure the accuracy of the authors’ report and would like to thank the referees for their constructive comments on the draft document. However, they do not accept liability for damages or losses arising from material published in this report.

The views expressed in this publication are those of the authors and not necessarily those of the HTA Programme or the Department of Health.

Objectives: To determine whether repetitive functional task practice (RFTP) after stroke improves limb-specific or global function or activities of daily living and whether treatment effects are dependent on the amount of practice, or the type or timing of the intervention. Also to provide estimates of the cost-effectiveness of RFTP.

Data sources: The main electronic databases were searched from inception to week 4, September 2006. Searches were also carried out on non-English-language databases and for unpublished trials up to May 2006.

Review methods: Standard quantitative methods were used to conduct the systematic review. The measures of efficacy of RFTP from the data synthesis were used to inform an economic model. The model used a pre-existing data set and tested the potential impact of RFTP on cost. An incremental cost per quality-adjusted life-year (QALY) gained for RFTP was estimated from the model. Sensitivity analyses around the assumptions made for the model were used to test the robustness of the estimates.

Results: Thirty-one trials with 34 intervention–control pairs and 1078 participants were included. Overall, it was found that some forms of RFTP resulted in improvement in global function, and in both arm and lower limb function. Overall standardised mean difference in data suitable for pooling was 0.38 [95% confidence interval (CI) 0.09 to 0.68] for global motor function, 0.24 (95% CI 0.06 to 0.42) for arm function and 0.28 (95% confidence interval 0.05 to 0.51) for functional ambulation. Results suggest that training may be sufficient to have an impact on activities of daily living. Retention effects of training persist for up to 6 months, but whether they persist beyond this is unclear. There was little or no evidence that treatment effects overall were modified by time since stroke or dosage of task practice, but results for upper limb function were modified by type of intervention. The economic modelling suggested that RFTP was cost-effective. Given a threshold for cost-effectiveness of £20,000 per QALY gained, RFTP is cost-effective so long as the net cost per patient is less than £1963. This result showed some sensitivity to the assumptions made for the model. The cost-effectiveness of RFTP tends to stem from the relatively modest cost associated with this intervention.

Conclusions: The evidence suggests that some form of RFTP can be effective in improving lower limb function at any time after stroke, but that the duration of intervention effect is unclear. There is as yet insufficient good-quality evidence to make any firm recommendations for upper limb interventions. If task-specific training is used, adverse effects should be monitored. While the effectiveness of RFTP is relatively modest, this sort of intervention appears to be cost-effective. Owing to the large number of ongoing trials, this review should be updated within 2 years and any future review should include a comparison against alternative treatments. Further research should evaluate RFTP upper limb interventions and in particular constraint-induced movement therapy, address practical ways of delivering RFTP interventions, be directed towards the evaluation of suitable methods to maintain functional gain, and be powered to detect whether RFTP interventions are cost-effective.

All abbreviations that have been used in this report are listed here unless the abbreviation is well known (e.g. NHS), or it has been used only once, or it is a non-standard abbreviation used only in figures/tables/appendices in which case the abbreviation is defined in the figure legend or at the end of the table.
Background

The repetitive practice of functional tasks is a component of current approaches to stroke rehabilitation. Practice may be augmented by strategies to enhance learning as used in movement science approaches, by mechanical means such as treadmills, or by strategies to encourage use of the affected limb in daily life by restraining the unaffected limb.

All these approaches have a core mechanism based on the repeated practice of functional tasks. This has the potential to be a resource-efficient component of stroke rehabilitation, including delivery in a group setting, or instructed practice in the home environment. This review considers the effectiveness and cost-effectiveness of all forms of repetitive functional task practice (RFTP).

Objectives

The aims of this study were:

- to determine whether RFTP after stroke improves limb-specific or global function or activities of daily living
- to determine whether treatment effects are dependent on the amount of practice, or the type or timing of the intervention
- to provide cost-effectiveness estimates for RFTP.

Methods

Data sources

The following searches were undertaken:

- electronic searches of Cochrane Stroke Trials Register, the Cochrane Library, MEDLINE, EMBASE, CINAHL, AMED, SportDiscus, ISI Science Citation Index, Index to Theses, ZETOC, PEDro and OT Seeker (all from inception to week 4, September 2006)
- electronic searches on non-English-language databases and for unpublished trials on MetaRegister, BioMed Central, CRISP, Centerwatch, National Research Register, ReFeR, Stroke Trials Directory, REHABDATA and CIRRIE (to May 2006)
- searches of conference proceedings, reference lists of existing systematic reviews, citation searching, publication on bulletin boards and author contact for all relevant trials.

Study selection

The review included randomised and quasi-randomised trials in adults after stroke, which included an intervention where an active motor sequence was performed repetitively within a single training session, where the practice aimed towards a clear functional goal and where the amount of task practice could be quantified. Studies using mechanical or behavioural strategies to facilitate or encourage functional task practice were also included. Primary outcomes included limb-specific or global functional measures. Secondary outcomes included measures of activities of daily living and adverse events.

Data extraction

Two reviewers independently screened titles and abstracts, extracted data and critically appraised the trials. Assessment of methodological quality was undertaken for allocation concealment, blinding, loss to follow-up, trial size and equivalence of treatment. Trialists were contacted for additional information.

Data synthesis

Standard Cochrane quantitative systematic review methods were used. A fixed-effect model was used, and results were expressed as weighted or standardised mean differences, with 95% confidence interval. Subgroup analyses were conducted for amount, timing and type of intervention, and for adequacy of allocation concealment, type of comparison group, equivalence of therapy time and trial size.

The measures of efficacy of RFTP from the data synthesis were used to inform an economic model. The model used a pre-existing data set and tested the potential impact of RFTP on cost. From the model an incremental cost per quality-adjusted life-year (QALY) gained for RFTP was estimated. Sensitivity analyses around the assumptions made for the model were used to test the robustness of the estimates.
**Results**

Thirty-one trials with 34 intervention–control pairs and 1078 participants were included. Overall, it was found that some forms of RFTP resulted in improvement in global function, and in both arm and lower limb function. Overall standardised mean difference in data suitable for pooling was 0.38 [95% confidence interval (CI) 0.09 to 0.68] for global motor function, 0.24 (95% CI 0.06 to 0.42) for arm function and 0.28 (95% confidence interval 0.05 to 0.51) for functional ambulation. Results suggest that training may be sufficient to have an impact on activities of daily living. Retention effects of training persist for up to 6 months, but whether they persist beyond this is unclear. There was little or no evidence that treatment effects overall were modified by time since stroke or dosage of task practice, but results for upper limb function were modified by type of intervention. The economic modelling suggested that RFTP was cost-effective. Given a threshold for cost-effectiveness of £20,000 per QALY gained, RFTP is cost-effective so long as the net cost per patient is less than £1963. This result showed some sensitivity to the assumptions made for the model. The cost-effectiveness of RFTP tends to stem from the relatively modest cost associated with this intervention.

**Conclusions**

**Implications for practice**

The evidence suggests that some form of RFTP can be effective in improving lower limb function at any time after stroke, but that the duration of intervention effect is unclear. There is as yet insufficient good-quality evidence to make any firm recommendations for upper limb interventions. If task-specific training is used, adverse effects should be monitored. While the effectiveness of RFTP is relatively modest, this sort of intervention appears to be cost-effective.

**Recommendations for future research**

Owing to the large number of ongoing trials, this review should be updated within 2 years. Any future review should include a comparison against alternative treatments. Further research should:

- evaluate RFTP upper limb interventions and in particular constraint-induced movement therapy
- address practical ways of delivering RFTP interventions
- be directed towards the evaluation of suitable methods to maintain functional gain
- be powered to detect whether RFTP interventions are cost-effective, include a baseline activities of daily living measure, include indirect costs and use quality of life as an outcome measure to facilitate economic analysis.
Chapter 1
Introduction

Description of the condition

The annual incidence of first ever stroke in the UK is approximately 100,000 people per year.\(^1\) Although the incidence of stroke is falling,\(^2\) stroke is still the major cause of long-term neurological disability in adults.\(^3\) The prevalence of disability and impairment varies according to sampling of cohorts, but approximately half of all stroke survivors are left with severe functional problems,\(^4\) and 53% are dependent on others for help with daily activities at 6 months after their stroke.\(^5\) Only 5–20% of people with initial upper limb impairment fully regain arm function, and 30–66% regain no functional use at 6 months.\(^6–9\) At 3 weeks and 6 months after stroke, 40% and 15% of people are unable to walk independently indoors,\(^9\) with only 18% regaining unrestricted walking ability.\(^10\) Initial grade of paresis is the most important predictor for motor recovery, with a longer recovery period for people with severe stroke.\(^11\)

Stroke is thus a leading cause of disability, and as such contributes to 4% of NHS costs.\(^12\) While stroke is a costly condition in the acute stage, over 40% of the 5-year cost of stroke is likely to be incurred subsequent to discharge, with 18% of the total cost being due to institutional care.\(^13\) If the disability and subsequent need for institutional care can be reduced, there is a potential for the long-term care costs to be substantially lowered.

Description of the intervention

Systematic reviews of treatment interventions for the paretic upper limb suggest that patients benefit from exercise programmes in which functional tasks are directly trained, with less benefit if the intervention is focused on the impairment, such as muscle strengthening.\(^14\) Although individual studies do not agree whether increased therapy intensity improves overall outcome, a recent meta-analysis\(^15\) has shown that more intensive therapy may at least improve the rate of recovery of activities of daily living (ADLs), particularly if a direct functional approach is adopted.\(^16\) Repetitive practice of goal-directed, functional movement under varying conditions for procedural learning is a feature of many forms of intervention in stroke rehabilitation. The use of intensive repetition is grounded in neurophysiological hypotheses about the reasons for loss of movement after stroke. Repeated motor practice enhances motor strength, speed and endurance, while sensorimotor coupling contributes to the adaptation and recovery of neuronal pathways.\(^17\) Repetitive task training (RTT) is common as a specific rehabilitation technique, but it is often combined with techniques to enhance cognitive involvement in the relearning of motor skills, such as functional relevance and knowledge of performance, thereby forming the underlying principles in the motor relearning or movement science physiotherapy approach.\(^18\)

Intensive periods of task practice using shaping techniques (progressively increasing the difficulty of a task in small steps and providing frequent feedback and positive encouragement) to build up to completion of a functional task are also a major feature of constraint-induced movement therapy,\(^19\) where they are combined with restricted use of the unaffected limb to overcome learned non-use or adaptive strategies.

Intensive practice of functional movement can also be assisted by treadmills,\(^20\) gait trainers\(^21\) or robotics.\(^22\) Mechanical assistance is used to overcome impairment which restricts the ability to participate, but also serves to deliver an intensity of training sufficient to develop the amount and power of movement required for functional performance.

Scope of the review

This study will consider the impact and cost-effectiveness of all three of the major forms of therapy that have repeated, functional task practice as a major component, namely repetitive task training (RTT), constraint-induced movement therapy (CIMT) and treadmill training (TM). In combination, these three forms of therapy will be referred to as repetitive functional task practice (RFTP).
Systematic reviews of TM\textsuperscript{20} and CIMT\textsuperscript{23} have already been published. To provide an overall picture of the relative effectiveness and cost-effectiveness of all the common forms of RFTP, the references from the systematic reviews for TM and CIMT were followed up and data were extracted from those primary studies that also met the inclusion criteria for this study. A systematic review of RTT studies has already been submitted to The Cochrane Collaboration by the authors of this report. This review therefore presents the results of these three interventions combined. The characteristics, quality and results of the trials for each intervention are reviewed and presented separately to ensure clarity, until combined in subgroup analysis to present a between-intervention overall estimate of efficacy and comparison of effect.

**Scope of the cost-effectiveness analysis**

An economic model will be developed from an existing data set. The data set contains information on the natural recovery and resource use of a cohort of stroke patients, which allows estimates to be made on outcomes and costs. The efficacy of RFTP and hence its potential impact on outcomes will be obtained from the review; the cost of RFTP will be estimated by considering staff and equipment costs. Using certain assumptions, which will be clearly outlined in the methods, the model data and the efficacy of RFTP from the review will be used to estimate the cost-effectiveness of RFTP. Uncertainty in the estimate will be considered by varying the parameters of any assumptions that are made.

**Objectives**

The objectives of this study were to carry out a systematic review and cost-effectiveness analysis to determine:

- whether RFTP improves global or limb-specific functional ability and ADL function in adults after stroke
- the factors that could influence primary outcome measures for RFTP, including the effect of amount, type and timing of intervention
- estimates of the cost-effectiveness of RFTP
Search strategy for identification of studies

Electronic searches

The Cochrane Stroke Group Trials Register was searched in October 2006, using the following parameters: Intervention Type: “Physiotherapy” or “Occupational Therapy”, without restriction of intervention code.

In addition, the following databases were searched as follows: The Cochrane Library (2006 Issue 3), MEDLINE (1966 to September week 4, 2006), EMBASE (1980 to week 40, 2006), CINAHL (1982 to October week 1, 2006), AMED (1985 to week 40, 2006), SportDiscus (1980 to October week 1, 2006), ISI Science Citation Index (1973 to 14 October 2006), Index to Theses (1970 to September 2006), ZETOC (to 14 October 2006), PEDro (to 3 October 2006), OT Seeker (to 21 April 2006) and OT Search (to March 2006).

The main search design was reviewed by the Cochrane Stroke Group Trials Search Coordinator. The MEDLINE search given below was used and adapted for other databases.

Unpublished trial data were searched for on national and international databases to May 2006 as follows: MetaRegister of Controlled Trials, BioMed Central, CRISP, Centerwatch, National Research Register, ReFeR, Stroke Trials Directory, REHABDATA and CIRRIE, using simple terms for stroke and rehabilitation or physical therapy. The China National Knowledge database was searched in both English and Chinese. Searching and translation of Chinese abstracts were undertaken by personnel from the Second Military Medical University, Shanghai.

### Other sources

**RTT**

The reference lists of systematic reviews relevant to physical or occupational therapy in stroke rehabilitation were searched.11,14–16,24–45 Reference lists of publications and literature reviews relevant to RTT identified by the search were combed to identify further relevant trials.36–48 In addition, forward citation searching was undertaken on ISI Web of Knowledge for all included trials, and the authors were contacted to ask for details of any other possible relevant trials, either published or unpublished. A request for information was also posted to the bulletin boards of World Congress of Physical Therapy and PHYSIO JISCmail.

**CIMT and TM**

Studies relevant to CIMT and TM were sourced from the search identified above, and also from existing systematic reviews.20,23 Only those trials of CIMT and TM that met the requirements of this review (i.e. RFTP intervention with suitable comparison) were included.

### Inclusion criteria

#### Types of study

Randomised and quasi-randomised trials (such as those allocating by date or alternation) were included in the review. Only the first period of cross-over trials was included.

One arm of the trial had to include RFTP, compared against usual practice (including ‘no treatment’) or an attention-control group. For trials of TM or CIMT, comparison groups using alternative forms of training were included.

Examples of attention-control treatment are comparable time spent receiving therapy on a different limb or participating in an activity with no
potential motor benefits. Usual-practice comparison
groups were accepted when the intervention
received by the control group was considered a
normal or usual component of stroke rehabilitation
practices, including neurophysiological or
orthopaedic approaches. Early after stroke it was
assumed that usual practice would mean that
patients would receive some therapy.

Types of participant
Adults (presumed 18 years and older) who had
suffered a stroke were included. Stroke was defined
according to the World Health Organization
(WHO) definition as “a syndrome of rapidly
developing symptoms and signs of focal, and at
times global, loss of cerebral function lasting more
than 24 hours or leading to death, with no
apparent cause other than that of vascular
origin”.49 Trials starting at any time after an acute
stroke and in any setting were included.

Types of intervention
Trials were required to include an intervention
where an active motor sequence was performed
repetitively within a single training session, where
the practice aimed towards a clear functional goal.
Functional goals could involve complex whole
tasks, or pretask movements for a whole limb or
limb segment such as grasp, grip or movement in
a trajectory to facilitate an ADL. To be included,
trials of repetitive activity were required to involve
complex multijoint movement with functional
measurement of outcome, rather than the exercise
of a single joint or muscle group orientated to
motor-performance outcomes.

Any intensity and duration of task training
schedule was included. However, trials were
included only if the duration or number of
repetitions within a session of practice, and the
number of sessions delivered, could be identified.
Trials clearly using motor relearning as a whole
therapy approach were included if the amount of
task-specific training received could be identified.

Trials using person-delivered, mechanical or
robotic movement assistance were included if the
purpose of the assistance was to facilitate a task-
related repetition. Trials combining repetitive task
practice with constraint of the unaffected limb
were also included.

Exclusion criteria
Trials were excluded if they combined RFTP
with other interventions such as electrical
stimulation virtual environments, biofeedback,
bilateral movement, or mental rehearsal.

Trials were also excluded if the intervention
used mechanical means simply to increase
endurance through the intensity of practice
without monitoring or adjustment according to
the quality of movement, such as the use of slot
machines.

Trial authors were contacted for clarification of
the nature of the intervention if it was unclear
whether the trial met the definition.

Types of outcome measure
Primary outcomes
The primary outcomes chosen were global and
limb-specific functional measures. Owing to the
large range of measures used across trials,
selection of outcome measures was done by
the review authors to maximise quantitative
pooling. If more than one measure was
available in an outcome category, measures of
functional motor ability used in the primary trials
were prioritised as follows in the different
categories. Items marked with an asterisk are
measures where a low score equals a positive
outcome. In all other measures, a high score
indicates a good outcome.

Upper limb function/reach
- Arm function: Action Research Arm Test
  (ARAT), Motor Assessment Scale (MAS) – upper
  limb component, Frenchay Arm Test, Wolf
  Motor Function Test (WMFT), Functional Test
  of the Hemiparetic Upper Extremity (FTHUE),
  Box and Block Test (BBT), Test Evaluant des
  Membres Supérieurs des Personnes Agées
  (TEMPA), University of Maryland Arm
  Questionnaire for Stroke, Motor Activity Log
  (MAL).
- Hand function: MAS hand, Jebsen Test of Hand
  Function*, Peg Test*, Purdue Pegboard.
- Sitting balance/reach: Reaching Performance
  Scale, Functional Reach.

Lower limb function/balance
- Lower limb function: walking distance, walking
  speed, functional ambulation, sit-to-stand*,
  measures of lower limb function, e.g.
  Rivermead Mobility Index, Sodring Motor
  Evaluation Scale (SMES), Step Test.

Overall functional ability
MAS, Rivermead Motor Assessment (RMA) Scale.
Secondary outcomes

ADL
Barthel Index (BI), Functional Independence Measure (FIM), Modified Rankin Scale, Global Dependency Scale.

Adverse outcome
Pain, injury, falls.

Timing of outcome assessment
Primary outcome timing was at the end of the intervention period. Where the end of the intervention period was not clearly defined, outcome measures at 3 months post-stroke were chosen as primary. Data are presented for follow-up less than 6 months post-stroke, and between 6 months and 1 year post-stroke.

Data extraction and assessment of study validity

Selection of studies
One reviewer (BF) performed the searches. From the initial references, 4443 obviously irrelevant items were excluded on title and abstract by one reviewer (BF) and checked by a second reviewer (JM). All reviewers (BF, JM, ML and LT) undertook screening on the same titles and abstracts until an acceptable level of inter-rater reliability was achieved (kappa = 0.63). From that point, two reviewers (from BF, JM, ML and LT) independently screened references.

In total, 447 full papers considered potentially relevant were retrieved, including 71 items in languages other than English. For non-English-language papers, decisions about exclusion were made on English abstract or machine translation of the abstract via WorldLingo or Translation Booth, if adequate. Where machine translation was inadequate, or where inclusion was unclear from English abstracts, the methods sections of full papers were commercially translated by native speakers. Seventeen methods sections of papers and three full non-English-language papers that were screened as potentially relevant were also commercially translated. Two reviewers independently screened all full papers and methods section translations for non-English studies. Altogether, 121 papers were progressed to more detailed filtering by two reviewers (from ML, LT, BF and JM).

Data extraction and management
All reviewers (BF, JM, ML and LT) undertook data extraction and critical appraisal on eight studies.

Using unweighted multiple kappa, inter-rater reliability of judgement of seven criteria for quality assessment was median kappa = 0.67 (range 0.48–0.85). Disagreements were reviewed and instructions for critical appraisal gradings revised. From that point, two reviewers independently conducted data extraction and review of the methodological quality of the eligible trials. Disagreements were resolved by discussion and referral to a third reviewer. Data were recorded on a standardised checklist, incorporating details of randomisation method, study population, intervention methods and delivery, reason for losses to follow-up, and post-therapy and follow-up outcome measures. In addition, information relating to treatment monitoring, acceptability and adherence was extracted where available.

Assessment of methodological quality
Items were evaluated as adequate, inadequate or unclear, and quality assessment was undertaken using the following criteria:

- selection bias
  - random allocation
  - allocation concealment
  - baseline comparability of groups
- performance bias
  - equal treatment of groups
- attrition bias
  - description of withdrawals, dropouts and those lost to follow-up
  - intention-to-treat analysis
  - percentage loss to follow-up
- detection bias
  - blinding of outcome assessors.

Analyses
The primary comparison to be undertaken was to estimate the overall effect of RFTP. Secondary comparisons were designed to determine whether treatment effects differed for type of intervention (RTT, CIMT or TM), or the timing or amount of intervention.

Measures of treatment effect
For continuous outcomes using similar measurement scales, the weighted mean difference (WMD) with 95% confidence interval (CI) was used. Where similar outcomes were measured using different outcome scales, results were combined using standardised mean difference (SMD) with 95% confidence interval. Outcomes measured using both dichotomous and continuous measurement units were analysed using the generic inverse variance method. For continuous outcomes, means of post-therapy scores and their
respective standard deviations were extracted. Changes from baseline outcome data were extracted if available across all trials.

Unit of analysis issues

Studies with multiple treatment groups

Two RTT trials compared upper versus lower limb training, so are included as four intervention–control pairs. In the subgroup analyses, these intervention–control pairs are not included as separate trials, as it was considered that the impacts of the interventions on upper and lower limb function in the same person would not be independent. Results for primary outcome of the lower limb training groups were selected, as studies were showing that treatment effects were greater for lower limbs. This strategy may have the effect of inflating effect sizes, but the effect should not bias the tests of subgroup effects. One RTT trial compared upper and lower limb training groups against the same control group. To avoid the control group being included twice, and to use a limb-specific rather than a global or an ADL measure, the lower limb training versus splint control comparison was selected for the subgroup analyses.

Dealing with missing data

If data were not in a form suitable for quantitative pooling, trial authors were contacted for additional information. Attempts were made to obtain post-therapy scores from trial authors who had reported median and interquartile ranges (IQRs).

Assessment of heterogeneity

The degree of heterogeneity for each outcome was assessed by the $I^2$ statistic. If less than or equal to 50%, any heterogeneity was deemed insubstantial and a fixed-effects meta-analysis was used. If the $I^2$ statistic was greater than 50%, the individual trial characteristics were explored to identify potential sources of heterogeneity. Meta-analysis was then performed using both fixed- and random-effects modelling to assess sensitivity to the choice of modelling approach and reported accordingly.

Clinical and methodological diversity was addressed by incorporation of subgroup analyses for type of participant (time from stroke), intervention (type and amount of intervention) and study design (allocation concealment, comparison group, equivalence of treatment, loss to follow-up and trial size).

To test for subgroup effects data were stratified by subgroup and the Q-statistic was partitioned from the unstratified analysis into ‘within subgroups’ and ‘between subgroups’. A $\chi^2$ test of the resulting between-subgroups Q-statistic was performed, using a 10% significance level.

Assessment of reporting biases

Assessment of the potential for reporting bias was checked by performing a subgroup analysis based on the trial size (number of participants) and producing a funnel plot of the standard error (of effect estimate) against effect estimate.

Subgroup analysis and investigation of heterogeneity

Planned subgroup analyses for upper and lower limb functional outcomes were undertaken as follows.

- Type of intervention: trials were classified as RTT, CIMT or TM.
- Dosage of task practice: this was calculated by multiplying the number of weeks by the number of sessions per week by the session duration in hours. Trials were divided into those providing up to and including 20 hours’ training and those providing more than 20 hours’ training in total. The division at 20 hours was based on the median value for dosage of task practice from all included trials, and the average length of stay in the National Sentinel Stroke Audit after the first 7 days of acute care, presuming the provision of 1 hour of training per day in the inpatient rehabilitation period.
- Time since stroke: mean time since stroke at recruitment was used to classify trials as within 0–6 months post-stroke or more than 6 months post-stroke. The division at 6 months was based on the interpretation of this as the main period of active rehabilitation. Because a number of trials recruited very early post-stroke, a post hoc analysis grouping was included for trials recruiting within 14 days of stroke.

It had been intended to consider whether effect sizes were related to whether training was based on pre-functional or functional activities or pre-intervention level of disability. In the event, most pre-functional trials were excluded because they contained passive or active-assisted movement, and levels of disability proved too difficult to classify because of mixed groups of participants and unsuitable measures and data for this purpose. Therefore, these planned subgroup analyses are not presented.

The selection of outcome measure for subgroup analysis was complicated by the fact that few trials
used similar outcome measures. Subgroup analyses were performed separately for upper and lower limb interventions. Outcomes for subgroup analyses were limited to measures of walking for lower limbs and arm function for upper limbs. If more than one measure was available, lower limb outcomes were prioritised in the following order: (1) walking speed, (2) walking distance and (3) functional ambulation/walking scales; and upper limb outcomes were prioritised as follows: (1) ARAT, (2) MAS – upper extremity (MAS-UE), (3) WMFT and (4) BBT. Outcome selection was based on evidence for correlation and similar responsiveness to change for walking distance, speed and functional ambulation.\textsuperscript{56} For measures of arm function, there is evidence for correlation and similar responsiveness to change for the MAS-UE and ARAT,\textsuperscript{57,58} and for correlation between ARAT and BBT.\textsuperscript{59} There is less evidence for correlation between WMFT and other tests, but ARAT, BBT and WMFT all correlate well with the Fugl–Meyer measure of arm impairment.\textsuperscript{59,60}

Four trials\textsuperscript{61–64} were omitted from the subgroup analyses because data were unsuitable for pooling. Of the remaining 27 trials, 26 presented means and standard deviations, so SMD could be used as the effect measure. One trial\textsuperscript{65} was excluded from the subgroup analyses because it used a dichotomous main outcome. This trial was excluded rather than using generic inverse variance, because SMD is easier for clinicians to interpret.

Planned subgroup analyses were also carried out for allocation concealment (adequate or inadequate/unclear). In addition, post hoc subgroup analyses were included to consider the impact of different comparison groups (attention-control, usual care), equivalence of therapy time (equivalent time, additional time) and trial size (under 25 participants, 25 participants and over), based on the median value. Planned subgroup analyses for intervention delivery (therapist versus self-administered, group versus individual) and intervention setting (home versus community) were not undertaken, because of insufficient numbers of trials.
Chapter 3
Description of studies

For the RTT search, 1366 records were identified from the Cochrane Stroke Trials Registry and 18,241 records from the main database searches, totalling 19,607. A further 772 records were added from unpublished trial databases, conference proceedings, and hand and citation searching, totalling 20,379. After removal of duplicates, 14,978 records progressed to filtering.

Figure 1 illustrates that, of the 447 papers retrieved, 360 studies were excluded as irrelevant when full-text details were seen. Thirty-four potentially relevant CIMT and TM studies were identified from existing systematic reviews, totalling 121 potentially relevant studies. Forty-four studies were excluded after more detailed filtering, leaving 77 studies identified as potentially appropriate for inclusion. Of these, eight are ongoing studies, of which one was identified from the Cochrane Stroke Trials Registry, four from handsearching, two from secondary referencing, and one from author contact. Thirty-eight studies are still awaiting assessment, because available information is insufficient to be able to make a decision. Seven of

---

**FIGURE 1** Flowchart of included and excluded studies
these were identified from the Cochrane Stroke Trials Registry, 20 from handsearching, three from database searching, five from secondary references and three from author contact.

Unpublished data were sourced from the trial authors for 11 RTT trials\textsuperscript{50,51,53,63–72} and two CIMT trials.\textsuperscript{73,74}

All of the included studies for RTT were identified from the Cochrane Stroke Trials Registry. For CIMT and TM, all of the included studies were identified from existing systematic reviews, except for one recent CIMT trial identified from the Cochrane Stroke Trials Registry.\textsuperscript{75}

**Description of studies**

Thirty-one studies were included in total, including 34 intervention–control pairs and data from 1078 participants relevant to this review. A description of included studies is presented separately for each of the three forms of RFTP, namely RTT, CIMT and TM. A summary of the characteristics of the included studies is given in Appendices 1–3.

**Included studies**

**RTT**

Fourteen trials were identified, comprising 17 intervention–control pairs, which met the inclusion criteria. Three trials included two relevant intervention–control pairs: Kwakkel and colleagues\textsuperscript{53} refer to a trial with two intervention–control pairs: a lower limb training group versus splint control, and an upper limb training group versus splint control. Blennerhassett and Dite\textsuperscript{50} also include two intervention–control pairs: an upper limb training group versus lower limb attention-control, and a lower limb training group versus an upper limb training attention-control. Two papers report on two intervention–control pairs of the same trial: Salbach and colleagues\textsuperscript{51} refer to a lower limb training group versus upper limb training attention-control, and Higgins and colleagues\textsuperscript{52} refer to an upper limb training group versus lower limb training attention-control.

In one trial\textsuperscript{71} there were three arms, consisting of a functional task practice group, a strength training group and a usual-care group. Only the data for the intervention–control pair of functional task practice versus control are included here.

**Design**

The 14 trials considered comprised 13 randomised controlled trials (RCTs)\textsuperscript{50,51,53,63–68,70–72,76–78} and one quasi-randomised trial.\textsuperscript{69} Four of the trials were identified as pilot RCT\textsuperscript{67,71,76,77} and three of the trials were multicentre.\textsuperscript{51,53,77} Three of the trials were stratified for randomisation: one for baseline level of walking deficit,\textsuperscript{51} one for gender and side of stroke,\textsuperscript{68} and one for severity of deficit.\textsuperscript{71}

**Sample size**

Four trials had 25 participants or fewer,\textsuperscript{66,67,69,76} six trials had between 25 and 49 participants,\textsuperscript{50,65,71,72,77,78} and five trials had 50 participants or more.\textsuperscript{51,53,68,70,71}

**Setting**

Of the 14 trials, three were carried out in Canada,\textsuperscript{51,65,67} three in Australia,\textsuperscript{50,66,78} three in the UK,\textsuperscript{69,70,77} one in Taiwan,\textsuperscript{72} one in the USA,\textsuperscript{71} one in The Netherlands\textsuperscript{53} and one in France.\textsuperscript{76}

**CIMT**

Eleven trials met the inclusion criteria. In four trials\textsuperscript{61,62,79,80} there were three arms consisting of a modified CIMT group, a traditional rehabilitation group and a no-treatment control group. In two of these trials the traditional rehabilitation group also received RTT, with the only difference between groups being constraint.\textsuperscript{79,80} In these trials, therefore, the no-treatment group was included as the comparison group. In the remaining two trials the data for the modified CIMT and traditional rehabilitation groups were included.\textsuperscript{61,62}

**Design**

All 11 trials were identified as RCTs, of which two were identified as pilot\textsuperscript{61,82} and two as preliminary,\textsuperscript{61,83} and one trial was labelled a ‘feasibility and efficacy’ study.\textsuperscript{80} All trials were single centre.

**Sample size**

Ten trials had 25 participants or fewer,\textsuperscript{61,62,73,74,79–84} One trial had 50 participants or more.\textsuperscript{64}

**Setting**

Nine trials were carried out in the USA,\textsuperscript{61,62,73,74,80–84} one in Saudi Arabia\textsuperscript{79} and one in Thailand.\textsuperscript{64}

**TM**

Six trials were identified which met the eligibility criteria. One trial with three arms consisted of two TM interventions, speed-dependent TM and limited progressive TM, compared with
conventional gait training. The limited progressive TM group was used in this review, as speed-dependent TM was judged to comprise two mechanisms of action.

**Design**

One study was a cross-over trial, of which only the first phase was used. The remaining five studies were RCTs. Of these five trials, one was identified as a pilot controlled trial. All of the trials were single centre. Three of the trials were stratified for randomisation, one for walking speed, one for deficit severity and age, and one for initial time to walk 10 m without assistance.

**Sample size**

Two trials had 25 participants or fewer, one trial had between 26 and 49 participants, and three trials had 50 participants or more.

**Setting**

Of the six trials, two were carried out in the USA, three in Germany, and one in Australia.

**Participants**

**RTT**

The 14 trials included 680 participants, of which 659 were included in the 17 intervention–control pairs relevant to this review. All of the trials included both genders, with three trials having more than 60% male participants. In two trials, the participants had a mean age of less than 60 years, and in five trials the mean age was over 70 years.

Six trials included only participants after a first stroke, and two trials included participants with either first or recurrent stroke. In the remaining trials, it was unclear whether inclusion was limited to first stroke only.

**Mean time since stroke**

Three trials recruited within 14 days of stroke, one trial recruited between 1 and 6 months post-stroke, and one trial recruited between 3 and 9 months post-stroke. The remaining trials recruited 12 months or more post-stroke.

**TM**

The six studies included 254 participants, of which data from 229 participants were relevant to this review. Five of the studies included both genders, as participants in one study were all male. Five studies had more than 60% male participants. Two trials had a mean age less than 60; no trials had a mean age more than 70 years.

Three trials included only subjects after a first stroke, one trial included subjects with either first or recurrent stroke, and in the remaining two trials it was unclear whether inclusion was limited to first stroke only.

**Mean time since stroke**

One trial recruited within the first month of stroke, one trial recruited within 3 months post-stroke, one trial recruited within 6 months post-stroke, and three trials recruited in the chronic phase of stroke recovery.

**Interventions**

**RTT**

Two trials used whole therapy motor approaches, and four trials trained single tasks, all related to balance, reach or sit-to-stand. The remaining trials consisted of mixed functional task training. Of these, three used a circuit-training approach. While all of the remaining trials included some functional task practice, this was sometimes mixed with other components, including strengthening exercise and...
TM, upper limb exercise, lower limb exercise and shaping training.

Of the 17 intervention–control pairs relevant to this review, four included lower limb or mobility training, one trained sit-to-stand movements, two trained balance in sitting and standing, one trained functional reach in sitting, and one trained standing balance and mobility. Six intervention–control pairs were upper limb training. Two intervention–control pairs used whole therapy approaches, training global function.

**Setting**

Four trials were carried out solely in an inpatient setting, four trials included both inpatient and outpatient care, four trials were carried out in outpatient or community settings, and two trials were in the home environment.

In three trials, the intervention was additional to usual care, of which two were during inpatient rehabilitation and one was after discharge from inpatient therapy, but additional to outpatient therapy.

**Amount of task practice**

The number of hours of training varied considerably across the interventions. Three trials provided less than 10 hours’ training in total, seven trials provided between 10 and 21 hours’ training, two trials provided more than 40 hours’ training and two trials prescribed more than 40 hours’ home-exercise therapy.

**Duration of training**

The length of time over which training was spread varied from 2 to 4 weeks for seven trials. For two trials, the length of time was estimated as 3 weeks of hospital inpatient therapy, with therapy for some patients in an outpatient setting if required. The intervention in four trials was over 6–8 weeks and in one trial the intervention was over 20 weeks.

**Intervention delivery**

All of the interventions were delivered by trained physiotherapists or occupational therapists, except for the self-monitored home-exercise programmes, where trained staff input was restricted to prescription and programme review, one trial where trained physiotherapy assistants provided balance training and one trial where registered practical nurses delivered sit-to-stand training. Three of the interventions were delivered in a group setting of between four and seven participants per group.

Of those programmes delivered in a circuit-class format, trial authors reported between 70 and 80% compliance. For the self-administered programmes in a home setting, trial authors reported 68–75% self-monitored adherence to the prescribed exercise programme.

**CIMT**

Trials were divided into those evaluating CIMT and those evaluating modified CIMT (mCIMT). CIMT interventions included wearing a padded mitten and/or sling to reduce use of the unaffected arm, together with a programme for improving task performance of the affected limb using techniques such as ‘shaping’ (progressively increasing the difficulty of a task in small steps and providing frequent feedback and positive encouragement) and repetitive task practice. Typically, therapy sessions lasted for 6 hours with participants attending 5 days per week. mCIMT comprised similar interventions, but therapy time was reduced to typically 1 hour per day with participants attending 3 days per week.

**Setting**

Two trials were carried out solely in an inpatient setting, and one trial included both inpatient and outpatient care. Seven trials were conducted in outpatient clinic settings, and the final study did not specify a setting, but given that participants were 3–9 months post-stroke it is likely to be an outpatient clinic setting.

**Amount of task practice**

The number of hours of training varied across trials, with those evaluating CIMT typically providing a larger number of hours, with a minimum of 42 hours and a maximum of 75 hours. Modified CIMT trials typically provided 30 hours’ training, with the exceptions of one trial where 15 hours’ training was provided, and another providing 20 hours’ training.

**Duration of training**

All CIMT trials spread training over 2 weeks, with the exception of one trial where training spanned 2.5 weeks. Trials evaluating mCIMT spread training over a longer period, typically 10 weeks, with the exception of one trial where training lasted for 2 weeks.

**Intervention delivery**

Interventions in eight trials were delivered by trained physiotherapists and/or occupational
therapists, with one trial also including delivery by ‘therapy assistants’. In three trials it is unclear who delivered the intervention. In the majority of trials, it is not clear whether interventions were delivered on a one-to-one or group basis. Exceptions are one trial where treatment was on a one-to-one basis, and one trial where participants were treated in groups of three to four.

TM
Two studies evaluated unsupported TM, and four studies evaluated bodyweight-supported treadmill training. One trial supported bodyweight to a maximum of 15%, one trial only allowed bodyweight support in the first three training sessions, and one trial progressively decreased bodyweight support as participants acquired greater self-support.

Two trials practised walking training with either a defined training heart rate or a target heart rate of 60–70%. The other trials did not specify a defined heart rate.

Five trials increased the belt speed of the treadmill during the intervention. One trial identifies the use of a treadmill with a variable belt speed, but does not specify how this was used.

Setting
Four trials were carried out in an inpatient setting and two trials in an outpatient setting. The four trials in the inpatient setting were in addition to usual care.

Amount of task practice
Only one trial provided more than 20 hours’ task practice.

Duration of training
The length of time over which training was spread varied from 2 to 4 weeks for four studies. For one study the length of time was 6 weeks and for one study it was 6 months.

Intervention delivery
All of the interventions were delivered by trained physiotherapists or occupational therapists.

Comparison interventions
RTT
Ten intervention–control pairs compared the intervention against an attention-control: two intervention–control pairs used a recreation or cognitive therapy control group, two intervention–control pairs from the same trial used a splint control and six (four from two trials) used a comparison training programme for the upper or lower limb.

Seven intervention–control pairs compared the intervention against usual care. Of these, three were during inpatient rehabilitation and provided equivalent hours of therapy, and one provided additional hours of therapy. The other three intervention–control pairs were after discharge from inpatient rehabilitation, and additional to any outpatient treatment. It is unclear whether the duration of therapy for the intervention–control pair was equivalent for one of these trials.

CIMT
Three studies compared the intervention against an attention-control. One trial used a bimanual neurodevelopmental therapy control group, one trial used procedures designed to focus attention on the affected limb without providing training in active movement, and one trial used a control designed to be less intense and designed to improve task performance with the unaffected side.

Three trials compared the intervention against usual care only. Control groups received an equal frequency of therapy time in two trials, and in one trial control participants received half the amount of therapy time compared with intervention participants.

A further three trials had two comparison groups, one receiving usual care and one receiving no treatment. Usual-care participants in all three trials received an equal amount of therapy to the intervention group; the no-treatment group received no interventions during the same period. Another trial also had two comparison groups, one receiving no treatment, the other an attention-control group that received the intervention without the restraint component.

The trial by Alberts and colleagues compared the intervention to no treatment, with participants randomised to the latter receiving the intervention 1 year later.

TM
One trial compared the intervention against an attention-control consisting of a home-exercise programme to lengthen and strengthen.
muscles. Two trials compared against an alternative intervention. One of these interventions was individual physiotherapy concentrated on walking rehabilitation, and one was based on common components of conventional therapy which would not normally have been received as participants were late post-stroke. Three trials compared the intervention against usual care. These trials were during inpatient rehabilitation and provided equivalent hours of therapy.

**Primary outcomes**

The 31 included trials used a wide range of different outcome measures, measurement statistics and time intervals for follow-up. Measures selected post-intervention are detailed below.

**Upper limb functional outcome measures**

**Arm**
- RTT: ARAT, WMFT, MAS – arm, BBT, FTHUE and Southern Motor Group Assessment – upper limb activity.
- CIMT: Action Research Arm Test and WMFT.

**Hand function**
- RTT: Nine Hole Peg Test (9HPT), Ten Hole Peg Test (10HPT), MAS – hand.
- CIMT: Grooved Pegboard Test, a key-turning task, and hand grip and pinch strength.

**Sitting balance/reach**
- RTT: reaching distance, Sitting Equilibrium Index, MAS – balanced sitting and lateral reach – time to return to quiet sitting.

**Lower limb functional outcome measures**

**Walking distance**
- RTT: Six Minute Walk Test (6MWT). Five Minute Walk Test (5MWT) and Six Metre Walk Speed (6MWS).
- TM: 5MWS and 10MWS and walking speed over 30 feet (9.1 m).

**Functional ambulation**
- RTT: Functional Ambulation Classification (FAC) and MAS – walking.
- TM: FAC.

**Sit-to-stand**
- RTT: Timed Up and Go (TUG) and MAS – sit-to-stand.
- TM: FAC.

**Lower limb functional measures**

**Walking speed**
- RTT: Ten Metre Walk Speed (10MWS) with walking aid. Five Metre Walk Speed (5MWS) at comfortable speed and Six Metre Walk Speed (6MWS).
- TM: 5MWS and 10MWS and walking speed over 30 feet (9.1 m).

**Functional ambulation**
- RTT: Functional Ambulation Classification (FAC) and MAS – walking.
- TM: FAC.

**Standing balance and reach**
- RTT: Upright Equilibrium Index, Functional Reach and Berg Balance Scale.
- TM: measures of standing balance using an instrumented balance assessment system which was not used.

**Global motor function**
- RTT: MAS and RMA score for gross functions.
- CIMT: none.
- TM: RMA score for gross functions.

**Secondary outcomes**

**ADL measures**
- RTT: BI and FIM. Two trials used the BI scoring out of 20, while the other trials used the scoring out of 100.
- TM: The BI.
- TM: none.

**Adverse events**
- RTT: number of falls.
- CIMT: levels of stiffness and discomfort on the affected side.
- TM: no trials reported quantitative data for adverse events. Narrative reports and reasons for withdrawal are summarised.

**Timing of outcome measurement**
- RTT: within the 0–6-month period post-stroke:
  - one trial measured outcome at 1 month post-intervention and three trials at 2 months post-intervention. Within the 6–12-month post-stroke period, one trial measured outcome at 6 months post-intervention, one trial at 9 months post-intervention, one trial at 6 months post-randomisation, and one trial at 1 year post-stroke.
• CIMT: one trial measured outcome 3–4 months post-stroke\textsuperscript{84} and one trial measured outcome 6 months post-intervention.\textsuperscript{74}
• TM: two trials measured outcome at 3 months post-intervention.\textsuperscript{87,89}

Excluded studies

There is a large number of excluded studies \((n = 44)\), described in Appendix 4. Because of the difficulties in determining whether trial interventions included task-specific functional repetition, the authors have attempted to be as transparent as possible about the basis on which trials were excluded. The reasons for exclusion were:

- not functional, or no functional outcome: nine studies
- mixed interventions, or interpreted as focusing predominantly on exercise: 11 studies
- not repetition, or unable to determine amount of practice: three studies
- passive movement: one study
- comparison group also includes some form of repetitive functional intervention: 11 studies
- methodological or reporting reasons: nine studies.

The excluded studies included three trials that had been either partially or fully translated from Chinese to English. While translation was undertaken by native-speaking health-service workers, there is the possibility that information was misinterpreted or misunderstood.

Ongoing studies

There are eight ongoing studies, where the information available is sufficient to say that the interventions include an element of RFTP. These are detailed in Appendix 5. Three trials involve training for standing, balance or sit-to-stand,\textsuperscript{90–92} two trials are of lower limb circuit training\textsuperscript{93,94} and one trial is of upper limb task-specific training.\textsuperscript{95} One trial uses a motor relearning approach (Langhammer B, Oslo University College, Oslo, Norway: personal communication, February 2006) and one trial is of CIMT.\textsuperscript{96} All are with participants in the early stages of stroke recovery, except for the trial by Langhammer.

Studies not assessed at report completion

RTT
Of the 17 studies categorised as unable to be assessed, 12 were ongoing studies identified from trials registers, where the information available was insufficient to be able to exclude them at this stage.\textsuperscript{97–108} Two studies are unpublished, and the reviewers are awaiting data.\textsuperscript{109,110} One study was published as a conference proceeding, and the reviewers were unable to contact the authors.\textsuperscript{111} Two studies are published, and attempts are being made to contact the authors to determine the exact content of the intervention.\textsuperscript{112,113}

CIMT
Of the seven studies awaiting assessment, three are ongoing\textsuperscript{114,115} (Page S, University of Cincinnati Academic Medical Centre, Ohio, USA: personal communication, February 2007). One recently published study was not in the date range for searching.\textsuperscript{75} Two related studies have recently completed and been submitted for publication.\textsuperscript{116} The reviewers were unable to contact the authors of one study to assess for eligibility.\textsuperscript{117}

TM
Of the 14 studies awaiting assessment, the information available for seven ongoing studies is insufficient to be able to exclude them at this stage.\textsuperscript{118–124} Three studies require translation.\textsuperscript{125–127} One study is recently completed\textsuperscript{128} as a follow-up to an included study,\textsuperscript{86} and three studies could not be traced.\textsuperscript{129–131}

Quality of included studies

Allocation

RTT
Allocation concealment was adequate in eight trials.\textsuperscript{50,51,53,67,70,71,77,78} In five trials, allocation concealment was unclear; of these, three trials stated that random allocation was used, but provided no description of the procedure for its concealment from those recruiting participants.\textsuperscript{68,72,76} One trial used coin flipping to randomise participants with no further description of the procedure,\textsuperscript{65} and one trial attempted concealment with a procedure involving participants drawing cards out of a box containing ten control group and ten experimental group cards, but the procedure for ensuring that those recruiting participants remained unaware of assignments is not described.\textsuperscript{66} One trial was quasi-randomised, allocating participants to intervention or control groups in alternate runs of five.\textsuperscript{59}

CIMT
The procedure for allocation concealment was unclear in all trials. Seven trials stated that random allocation was used, but provided no description
of the procedure. 61,62,73,79,80,83,84 Four trials stated use of tables of random numbers to allocate participants to intervention or control groups, with no description of the procedure. 64,74,81,82

**TM**
Allocation concealment was adequate in four trials. 64–89 In two trials, allocation concealment was unclear. One trial stated that participants were assigned to groups by block randomisation on the basis of walking speed, but provided no description of the procedure for concealing the allocation, or the block length. 85 One trial stated randomisation, with no description of the procedure. 63

**Blinding of outcome assessors**

**RTT**
Blinding of primary outcome assessment was stated in all but two trials. 69,71 Of the studies that stated observer blinding, three gave no details of how this was done. 68,72,75 Four trials checked whether the outcome assessor had become unblinded, 51,53,67,70 and out of these, three trials reported that some degree of unmasking might have occurred. 51,53,67

**CIMT**
Blinding of outcome assessment was attempted in all trials with the exception of one trial, 79 where there was no mention of blinding. In two trials, 73,84 action taken at blinding was judged likely to have been effective, for example employing personnel from outside the hospital who were blind to treatment assignment. Eight trials stated that outcome assessment was blinded, but did not describe the procedure. 61,62,64,74,80–83 No trial reported checking for the possibility that unblinding had occurred.

**TM**
Blinding of primary outcome assessment was stated in two trials. 85,87 Neither trial described checks for unblinding. Two trials attempted blinding, but report that this may not have been successful, 88,89 for example one trial stated that as a result of staffing limitations and institutional safety regulations, treadmill exercise testing was conducted by the same staff who provided training. 88 Hence metabolic fitness tests were unblinded. In one trial, physiotherapists not involved in the therapy were responsible for the assessment of the RMA Scale, but disclosure by patients and team-mates could not be fully excluded. 89 One trial did not mention blinding of outcome assessors to participants’ treatment status. 86

Owing to the nature of the interventions, blinding of participants, intervention providers or usual care providers was not assessed, as it is essentially impractical in this type of study.

**Follow-up and exclusions**

**RTT**
All trials provided information about numbers of withdrawals and reasons for withdrawal. All trials accounted for all participants at the end of the trial, except for one, which included participants in the analysis only if they completed the treatment programme. 71 Of the 14 trials in total, three trials had 10–20% loss 53,68,78 and two trials had more than 20% loss. 67,70 The remaining nine trials had less than 10% loss to follow-up.

**CIMT**
Nine trials had no withdrawals. 61,62,64,73,74,79,80,82,83 One trial provided information about numbers of withdrawals and reasons for withdrawal; 84 and one trial 81 states overall numbers of withdrawals, but not by intervention group. All except one trial 81 accounted for all participants at the end of the trial. All trials had no loss to follow-up, except for one trial with 13% loss 81 and one trial with 29% 84

**TM**
Five trials provided information about numbers of withdrawals and reasons for withdrawal, and accounted for all participants at the end of the trial. Withdrawals and follow-up were unclear in one trial. 85 Two trials had less than 10% loss to follow-up post-treatment, 87,89 two trials had 11–20% loss to follow-up post-treatment 85,86 and one trial had more than 20% loss to follow-up post-treatment. 88

**Other potential sources of bias**
To detect systematic differences in care provided to participants in comparison groups other than the intervention under investigation, trials were assessed to determine whether groups were treated equally during the intervention and during usual care.

**RTT**
During the intervention, groups were treated equally in all trials, with the following exceptions: in one trial 70 there was no significant difference in the amount of treatment; however, the authors state in a supplementary paper that there may have been differences in elements of treatment such as detailed feedback and social conversation. 132 In one trial it is not clear whether groups were treated equally 72 and in two trials participants in the intervention group received
additional hours of therapy. During usual care, groups were treated equally in eight trials. In four trials no information is provided and in a further two trials there was no usual-care group.

**CIMT**

During the intervention, comparison groups receiving therapy were treated equally in all except two trials. In one trial, participants in the intervention group spent 7 hours at the rehabilitation centre each weekday for 2 weeks; the comparison group received only four 10-minute periods encouraging them to focus on performing new activities with the affected upper extremity at home and two sessions of 'physical therapy', plus a range of exercises to carry out at home. (As it was unknown how long control group participants practised, equivalence of therapy time was assumed for subgroup analyses.) In another trial, participants in the intervention arm of the trial similarly received longer periods of therapy (6 hours per day over 8 weekdays and 4 hours per day over 2 weekend days) than the comparison group (3 hours per day over 8 weekdays and 2 weekend days of rest). Groups were treated equally in all trials with a usual-care comparison.

**TM**

During the intervention, other than the intervention provided, groups were treated equally in all except one trial, where the control group was given a home-exercise programme to carry out for the same number of sessions as in the intervention group. However, this programme was not prescribed in sufficient number or intensity to provide a training effect and instead aimed to provide a credible sham programme. Groups were treated equally in all trials with a usual-care comparison.
Chapter 4

Results of the review

Primary outcomes

Results are presented separately for upper and lower limb outcomes and global function, concluding with an overall treatment effect for all forms of RFTP on functional outcome. All results are post-therapy, except for Langhammer and Stanghelle,68 which are 3 months post-stroke, and Van Vliet and colleagues,70 which are 3 months post-baseline.

Upper limb function: post-therapy

Results are presented for arm function, hand function, and sitting balance and reach.

Arm function

Eighteen trials recruiting 634 participants measured arm function, with data suitable for pooling available for 76% (n = 485) (Figure 2). There was some heterogeneity of treatment effects

FIGURE 2 Arm function
although not sufficient to merit the use of a random-effects approach.

Eight RTT trials recruited 467 participants, with data available for 88% (n = 412) of participants. Ten CIMT trials recruiting 167 participants, with data available for 88% (n = 143) of participants. In three of the CIMT trials with 91 participants in total, data were unsuitable for pooling. Page and colleagues (2002) included outcome data for nine participants, and provided means with no standard deviations (ARAT: CIMT group mean change +11.5, traditional therapy group mean change +1.4). Page and colleagues (2004) included data for 13 participants, and also provided means with no standard deviations (ARAT: CIMT group mean change +11.4, traditional therapy group mean change +7.1). Suputtitada and colleagues reported median and ranges for 69 participants (ARAT: CIMT group median 55, range 30–57, control group median 47.5, range 15–54). Of the remaining seven CIMT trials with 76 participants, data were available for 96% (n = 73).

The pooled effect for the impact of RFTP on arm function across all trials showed a small effect size, which was statistically significant: (SMD 0.24, 95% CI 0.06 to 0.42).

Hand function

Seven trials recruiting 357 participants measured hand function, with data available for 86% (n = 307) (Figure 3). Five RTT trials recruited 324 participants, with data available for 87% (n = 281) of participants. Two CIMT trials recruited 33 participants, with data available for 79% (n = 26). The pooled effect for RFTP on hand function across all trials was small, and marginally statistically non-significant (SMD 0.19, 95% CI –0.03, 0.42).

FIGURE 3 Hand function
Sitting balance/reach

Five trials (all RTT) recruiting 256 participants measured sitting balance or functional reach (Figure 4).\textsuperscript{56,68,70,77} Data were available for 82\% (\( n = 210 \)). There was some heterogeneity of treatment effects (\( I^2 = 32\% \)), although not sufficient to merit the use of a random-effects approach.

The impact on sitting balance/reach showed a small effect size that was not statistically significant (SMD 0.23, 95\% CI –0.05 to 0.50).

Upper limb function: follow-up

Under 6 months post-therapy

One CIMT trial measuring hand function\textsuperscript{84} and two RTT trials measuring sitting balance,\textsuperscript{76,77} recruiting 78 participants in total, measured for retention effects between post-therapy and under 6 months post-therapy (Figure 5). Data were available for 86\% (\( n = 67 \)) and effects across trials were homogeneous (\( I^2 = 0\% \)). There was a moderate effect size, which was statistically significant (SMD 0.55, 95\% CI 0.06 to 1.04).

Between 6 and 12 months post-therapy

Four trials\textsuperscript{50,68,70,71} (all RTT) recruiting 254 participants measured arm function for retention effects between 6 and 12 months post-therapy (Figure 5). Data were available for 76\% (\( n = 195 \)). Effects across trials were homogeneous (\( I^2 = 0\% \)). Results showed no effect of treatment (SMD –0.02, 95\% CI –0.31 to 0.26).

Subgroup analysis: upper limb function

Subgroup analyses for upper limb interventions are based on trials providing measures of arm function. Trials that only provide measures of hand function\textsuperscript{84} or sitting balance/reach\textsuperscript{56,76,77} are therefore excluded. Subgroup analyses are presented for type, amount and timing of intervention, and to consider the impact of

specific trial features on the results. The classification of trials for each subgroup analysis is given in Appendix 6.

**Type of intervention**

Subgroups compared the treatment effects for eight RTT trials recruiting 467 participants, and seven CIMT trials recruiting 76 participants (Figure 6). The impact of RTT on upper limb function post-treatment just failed to reach statistical significance (SMD 0.17, 95% CI –0.03 to 0.36). The impact of CIMT on arm function showed some heterogeneity ($I^2 = 41\%$), but not sufficient to necessitate the use of a random-effects approach. There was a large and statistically significant effect size (SMD 0.77, 95% CI 0.26 to 1.29). The difference between effect sizes for CIMT and RTT was statistically significant ($p = 0.03$).

**FIGURE 6** Subgroup analysis: type of intervention – upper limb trials
Dosage of task practice
Seven trials (five RTT, two CIMT) with 399 participants provided up to 20 hours’ task practice. Eight trials (three RTT, five CIMT) with 163 participants provided more than 20 hours’ task practice (Figure 7). There was substantial heterogeneity ($I^2 = 50.8\%$) in the trials providing up to 20 hours’ task practice. Using a random-effects model to combine the effects from individual trials, while the estimated effect was greater for the subgroup with more than 20 hours of task practice, the difference between subgroups failed to reach statistical significance ($p = 0.18$).

Results of the review

Review: Repetitive functional task practice (including RTT, CIMT, TM)
Comparison: 03 Subgroup analyses: upper limb
Outcome: 02 Dosage of task practice

FIGURE 7 Subgroup analysis: dosage of task practice – upper limb trials
Time since stroke
Nine trials (four RTT, five CIMT) with 364 participants measured arm function in participants up to 6 months post-stroke (Figure 8). There was some heterogeneity in trials 0–6 months post-stroke ($I^2 = 34.8\%$), but not sufficient to warrant using a random-effects model. The difference between subgroups did not reach statistical significance ($p = 0.65$).

FIGURE 8 Subgroup analysis: time since stroke – upper limb trials
Allocation concealment

Trials were grouped according to whether allocation concealment was judged to be adequate (five RTT trials) or inadequate/unclear (ten trials: three RTT, seven CIMT) (Figure 9). There was some heterogeneity observed in the ‘inadequate/unclear’ subgroup ($I^2 = 27.3\%$). The difference between subgroups was statistically significant ($p = 0.08$), indicating that the effect of RFTP was greater for trials where allocation concealment was either inadequate or unclear.

FIGURE 9 Subgroup analysis: allocation concealment – upper limb trials
Post hoc analysis: type of comparison group

Seven trials (five RTT, two CIMT) were classified as usual care or alternative treatment, and eight trials (three RTT, five CIMT) were classified as attention-control or no treatment (Figure 10), with some heterogeneity observed in trials with usual care/alternative treatment controls ($I^2 = 46.1\%$). There was no statistically significant difference between subgroups ($p = 0.84$).

FIGURE 10 Subgroup analysis: type of comparison group – upper limb trials
Post hoc analysis: equivalence of therapy time

One subgroup comprised seven trials (two RTT, five CIMT) which gave, additional therapy time to the experimental group, and the other contained eight trials (six RTT, two CIMT) where therapy time for experimental and control groups was equivalent (Figure 11). There was some heterogeneity of treatment effects in each subgroup, but not sufficient to merit the use of a random-effects meta-analysis. There was no significant difference between the two subgroups (p = 0.92).

Post hoc analysis: trial size

The median number of participants in the trials was 23. A post hoc analysis was therefore undertaken for trials with under 25 participants versus those with 25 or more participants (Figure 12). Some heterogeneity was observed in trials with under 25 participants ($I^2 = 38.2\%$), but not enough to warrant the use of a random-effects model. The difference between effect sizes in the small trial sub-group (<25 participants) and the larger trial sub-group (≥25 participants) was statistically significant (p = 0.06). As the effect in the small trial subgroup (SMD 0.62, 95% CI 0.18 to 1.07) is significantly larger than in the larger trial subgroup (SMD 0.16, 95% CI –0.04 to 0.36), this may indicate some degree of reporting bias in upper limb trials. This is supported by the funnel plot in Figure 13, which has some apparent asymmetry indicating a potential lack of reporting of small negative trials with large standard errors.

**FIGURE 12** Subgroup analysis: trial size – upper limb trials

**FIGURE 13** Funnel plot of precision versus effect size – upper limb trials
Lower limb function: post-therapy
Results are presented for walking distance, walking speed, functional ambulation, sit-to-stand, lower limb functional measures and standing balance/reach. All results are post-therapy, except for Langhammer and Stanghelle,\textsuperscript{68} which is 3 months post-stroke, and Van Vliet and colleagues,\textsuperscript{70} which is 3 months post-baseline.

Walking distance
Seven trials included a measure of walking distance (Figure 14). All results are change from baseline scores except for Macko and colleagues,\textsuperscript{88} and are expressed as metres walked in 6 minutes. The degree of heterogeneity ($I^2 = 49.1\%$) in the effect sizes of the seven trials was very close to the study criterion for 'substantial' heterogeneity, so a random-effects model was used. Three RTT trials\textsuperscript{50,51,67} recruiting 133 participants measured walking distance, with outcome data available for 98\% ($n = 130$) of participants. Four TM trials\textsuperscript{86–89} recruiting 155 participants measured walking distance, with outcome data available for 96\% ($n = 149$).

For RTP overall, pooled results showed a statistically significant difference (WMD 50.05 m, 95\% CI 29.65 to 70.44 m). Owing to the lack of homogeneity of standard deviations, resulting in a substantial impact on the weighting of several trials, results were reanalysed using the SMD and a random-effects model. The result showed a large effect size, which remained highly statistically significant (SMD 0.98, 95\% CI 0.58 to 1.39, excluding Macko and colleagues,\textsuperscript{88} which did not provide 'change-from-baseline' data). To improve comparability with effect sizes for other outcomes and for use in the economic analysis, the SMD based on the post-treatment data from the seven trials was also computed (SMD 0.45, 95\% CI 0.20 to 0.70; figure not shown). As expected, the SMD based on the post-treatment data is considerably smaller than that based on the change-from-baseline data, primarily owing to its poorer sensitivity to change.

Walking speed
Ten trials included a measure of walking speed (Figure 15). Results were converted into metres per

FIGURE 15  Walking speed

second, with the exception of Dean and Shepherd,\(^66\) and Van Vliet and colleagues,\(^70\) who presented statistics for the number of seconds to walk 10 m and 6 m, respectively. There was some heterogeneity of treatment effects ($I^2 = 8.7\%$), although not sufficient to merit the use of a random-effects approach. Five RTT trials recruited 311 participants,\(^51,53,66,67,70\) with outcome data available for 85% ($n = 263$) of participants. Six TM trials recruited 229 participants.\(^63,85–89\) One TM trial with 30 participants provided data unsuitable for pooling, with data for mean distance walked but no standard deviations.\(^63\) Of the five remaining trials with 199 participants, outcome data were available for 87% ($n = 173$) of participants.

Overall, pooled results for the impact of RFTP on walking speed showed a small effect size, which was statistically significant (SMD 0.28, 95% CI 0.09 to 0.47). A subgroup analysis was undertaken for walking speed measured over short (5 or 6 m) or medium (10 m) distances, with no significant difference found ($p = 0.57$).

Functional ambulation
For RFTP overall, seven trials recruiting 368 participants measured functional ambulation, with outcome data available for 79% ($n = 291$) (Figure 16). Effects across trials were homogeneous ($I^2 = 0\%$). Five RTT trials\(^53,68,70,76,78\) recruited 295 participants, with outcome data available for 81% ($n = 238$). Two TM trials\(^85,86\) recruited 59 participants, with outcome data available for 89% ($n = 53$).

Pooling the results from seven trials showed RFTP to have a statistically significant but small effect on functional ambulation measures (SMD 0.28, 95% CI 0.05 to 0.51), with no significant difference in effects between RTT and TM ($p = 0.66$).

Sit-to-stand
Seven trials (all RTT) recruiting 397 participants included a measure of sit-to-stand,\(^50,51,65,67,68,70,77\) with outcome data available for 87% ($n = 346$) (Figure 17).

Effects across trials were homogeneous ($I^2 = 0\%$), showing a small to moderate effect size, which was

FIGURE 17 Sit-to-stand
statistically significant (standardised effect size 0.39, 95% CI 0.18 to 0.61).

**Lower limb functional measures**

Four trials (all RTT) recruiting 223 participants included a measure of lower limb function, with outcome data available for 79% (n = 177) (Figure 18). Effects across trials were homogeneous (I² = 0%).

Results overall showed a small effect size, which was not statistically significant (SMD 0.20, 95% CI -0.10 to 0.50).

---

**Standing balance and reach**

Three trials (all RTT) recruiting 137 participants measured standing balance or functional reach, with outcome data available for 96% (n = 132) (Figure 19).

Effects across trials were homogeneous (I² = 0%), showing a small effect size, which was not statistically significant (SMD 0.29, 95% CI -0.06 to 0.63).
Lower limb: follow-up

**Under 6 months post-therapy**

Six trials (four RTT67,76–78 and two TM87,89) recruiting 174 participants measured some aspect of lower limb function for retention effects between post-therapy and under 6 months post-therapy (Figure 20). Outcome data were available for 90% (n = 155). Effects across trials were homogeneous ($I^2 = 0\%$). Results showed a small to moderate effect size which was statistically significant (SMD 0.37, 95% CI 0.05 to 0.69).

**Between 6 and 12 months post-therapy**

Three RTT trials recruiting 211 participants measured some aspect of lower limb function for retention effects of RTT interventions between 6 and 12 months post-therapy (Figure 20).50,68,70 Outcome data were available for 80% (n = 170).

There was some degree of heterogeneity of treatment effects ($I^2 = 49.1\%$), although not sufficient to merit the use of a random-effects approach (and the small effect size precludes the need to perform a sensitivity analysis on the choice of analytic approach). Results showed no treatment effect (SMD −0.01, 95% CI −0.32 to 0.29).

**Subgroup analyses: lower limb function**

Subgroup analyses for lower limb interventions are based on trials providing measures of walking function (walking distance, walking speed or functional ambulation rating). Trials that only provide measures of standing balance/reach76 or sit-to-stand65,77 are therefore excluded. Subgroup analyses are presented for type, amount and timing of intervention, and to consider the impact of adequacy of allocation concealment.

![FIGURE 20 Lower limb follow-up at 0–6 months and more than 6 months post-therapy](image-url)
and type of comparison group. There were insufficient trials providing additional therapy time or trials of fewer than 25 participants to undertake subgroup analyses. The classification of trials for each subgroup analysis is given in Appendix 6.

**Type of intervention**

Twelve trials (seven RTT, five TM) included a measure of walking ability (Figure 21). There was some heterogeneity of treatment effects within each subgroup, but not sufficient to merit the use of random-effects analysis.

There was no statistically significant difference between RTT and TM interventions ($p = 0.62$).

**Dosage of task practice**

Nine trials (five RTT, four TM) provided up to 20 hours’ training time and three trials (two RTT, one TM) provided more than 20 hours’ training time (Figure 22). There was substantial heterogeneity in the more than 20 hours’ practice subgroup ($I^2 = 59.4\%$), so a random-effects model was used. There was no statistically significant difference between subgroups ($p = 0.65$).

**Time since stroke**

Six trials (three RTT, three TM) recruited 0–6 months post-stroke and six trials (four RTT, two TM) recruited more than 6 months post-stroke (Figure 23). There was some heterogeneity of treatment effects in both subgroups, but not

sufficient to merit a random-effects analysis. There was no significant difference between subgroups ($p = 1.0$).

**Allocation concealment**

Trials were grouped according to whether allocation concealment was judged adequate (eight trials: six RTT, two TM) or inadequate/unclear (four trials: one RTT, three TM) (Figure 24). There was heterogeneity within each subgroup, but insufficient to warrant using a random-effects meta-analysis. There was no statistically significant difference between subgroups ($p = 0.51$).

**Post hoc analysis: type of comparison group**

Six trials (two RTT, four TM) were classified as usual care or alternative treatment, and six trials (five RTT, one TM) as attention-control or no treatment (Figure 25). There was some

---

**FIGURE 22** Subgroup analysis: dosage of task practice – lower limb trials
heterogeneity within each subgroup, but insufficient to warrant the use of a random-effects meta-analysis. The difference between subgroups was marginally non-significant ($p = 0.10$), with the estimated effect somewhat larger for the attention-control/no treatment subgroup.

**Trial size**

No trials of lower limb interventions had fewer than 25 participants, so subgroup analysis was not undertaken. The funnel plot in Figure 26 does not suggest reporting bias.

**FIGURE 23** Subgroup analysis: time since stroke – lower limb trials

FIGURE 25 Subgroup analysis: type of comparison group – lower limb trials

FIGURE 26 Funnel plot of precision versus effect size – lower limb trials
Global motor function

Two RTT trials\(^68,70\) recruiting 181 participants measured global motor function (Figure 27). Outcome data were available for 76\% (\(n = 138\)). Three TM trials\(^63,88,89\) recruiting 105 participants measured global motor function. Data were not suitable for pooling from two trials.\(^63\) One trial\(^89\) showed no significant difference in RMA score for gross functions, but provided median and IQR scores only: experimental group median 11 (IQR 11–11), control group median 11 (IQR 10–11).

The trials with outcome data suitable for pooling showed a small to moderate effect size which was statistically significant (SMD 0.38, 95% CI 0.09 to 0.68).

Overall summary analysis

The primary analysis requires an overall estimate of the effect of RTFTP on functional outcome (Figure 28). To gain an overall measure of RTFTP as a preliminary basis for the economic analysis, a summary plot was constructed, with subcategories for the different intervention types. Some RTT trials included both upper and lower limb intervention–control pairs. To avoid their being included twice, the lower limb intervention–control group was chosen, as it is known that lower limb treatment effects are more likely. By privileging lower limb outcomes, this would have the effect of providing a slightly inflated overall effect size.

Twenty-six intervention–control pairs with 876 participants provided data suitable for pooling, with outcome data available for 88\% (\(n = 775\)). Figure 28 shows that the overall treatment effect of RTFTP (with selection of lower limb functional outcomes in studies with multiple intervention–control pairs, or in studies with both upper and lower limb intervention) was small to moderate and statistically significant (SMD 0.34, 95% CI 0.19 to 0.48).

If selection is based on upper limb functional outcomes from trials with multiple intervention–control pairs, or in studies with both upper and lower limb intervention, the results are small and statistically significant (SMD 0.26, 95% CI 0.12 to 0.41), indicating that the findings are not particularly sensitive to the choice of lower limb rather than upper limb outcomes.

Secondary outcomes

ADL function

Five RTT trials with seven intervention–control pairs\(^{51,53,68,70,76}\) and recruiting a total of 399 people used a measure of ADL, with data available for 81% (\(n = 325\)) (Figure 29). One CIMT trial\(^{81}\) recruiting 23 participants used a measure of ADL, with data available for 87% (\(n = 20\)). No TM trials included ADL data. For RFTP overall, six trials recruiting 422 participants included a measure of ADL, with outcome data available for 82% (\(n = 345\)).

Results showed a small statistically significant effect size (SMD 0.30, 95% CI 0.09 to 0.52).

Adverse effects

One RTT trial of sit-to-stand training\(^{65}\) presented data for the number of falls: intervention group 3/25 (12%) versus control group 4/23 (17.4%), (odds ratio 0.65, 95% CI 0.13 to 3.27). No other trials presented data for adverse events, but two trials narratively reported no adverse effects.\(^{76,78}\) In one trial,\(^{51}\) intervention-related reasons for withdrawal that could be interpreted as adverse events included one person out of 47 in a mobility-training group who experienced the onset of groin pain. Four participants also fell during the mobility intervention, but did not suffer injury and continued to participate in the group. Two falls also occurred during evaluation. No other trials reported intervention-related reasons for withdrawal.

Eight CIMT trials did not mention adverse events,\(^{61,62,64,74,79,80,82,83}\) although four of these trials stated that participants were highly satisfied with the protocol.\(^{61,79,80,82}\) A further two trials stated there were no adverse events,\(^{81,84}\) with one trial author commenting further that there was no

---

**FIGURE 29 ADL function**
In one trial, the first three participants to receive restraint reported stiffness and discomfort on the involved side half-way through the 2-week treatment period. These effects were associated with overuse of the affected limb and led to modification of the intervention protocol for the fourth participant, with motor demands increasing more slowly. The fourth participant reported no muscle soreness. There were no intervention-related reasons for withdrawal in any CIMT or mCIMT trial. Of the six TM trials, three reported that there were no adverse events. There are no reports of adverse events in three trials. None of the trials reported intervention-related reasons for withdrawal that could be interpreted as adverse events.

**Sensitivity analysis**

A sensitivity analysis was undertaken to evaluate the effect on upper limb outcomes of including cross-over and quasi-randomised trials, finding no substantive difference between including (SMD 0.24, 95% CI 0.06 to 0.42) and not including (SMD 0.24, 95% CI 0.05 to 0.43) these trials. A sensitivity analysis was also undertaken on lower limb trials to evaluate the effect of excluding studies with more than 20% loss to follow-up (only one upper limb trial had loss to follow-up of greater than 20%). The effect of RFTP was significantly greater ($p = 0.02$) for trials with loss to follow-up of 20% or less (SMD 0.42, 95% CI 0.22 to 0.63) than for trials with more than 20% loss to follow-up (SMD −0.06, 95% CI −0.39 to 0.27).
Chapter 5
Economic analysis

Background
The systematic review identified studies that will potentially alter patient outcomes by using RTT. There were three forms of therapy that had RTT as a major component: RTT, CIMT, and TM. The therapies will subsequently be referred to as RFTP. The economic modelling reported below was designed to determine whether RFTP is cost-effective.

Study question
From the perspective of the NHS, is RFTP for stroke (in addition to usual care) cost-effective over 3 years as judged by the incremental cost per quality-adjusted life-year (QALY) gained?

Perspective
The analyses performed took the perspective of the NHS and Personal Social Services (PSS). The cost of stroke tends to be higher in the acute stage owing to the inpatient cost. Once a patient is discharged from hospital, some of the costs will be borne by the NHS through provision of therapy and aids, and some will be borne by PSS through provision of support services. RFTP would take place after the acute stage of treatment and hence will have no effect on these costs; therefore they are not considered in this analysis.

Current treatment
At present, the amount of physical therapy input to post-stroke patients varies widely. In hospital, most patients receive physiotherapy and occupational therapy. Once their care is transferred into the community, the provision of therapies is much less structured. This means that it is difficult to define a standard package of physical therapy after stroke. For this analysis usual care was based on observations of a cohort of patients treated in the NHS over time with the amount of physical therapy varying between patients. For the cost analysis the alternative treatments compared here are usual care and usual care plus RFTP.

Methods
Form of evaluation
A cost–utility approach was adopted, assessing gains in QALYs. The authors believe this to be the most meaningful outcome measure on which to base the economic evaluation. The nature of RFTP means that it will not directly prevent death, excluding a cost-effectiveness analysis of life-years gained. An alternative would be to express the effects of RFTP in terms of a change in units of some measure of function; however, the authors believe that this would be generally less meaningful than identifying a cost per QALY gained. The modelling is based over a 3-year period.

Choice of RFTP intervention
The economic analysis is based around the three forms of therapy described in the systematic review: RTT, CIMT and TM.

Measures of benefit
The health outcome summary measure is the number of QALYs gained. A health outcome was needed that could be used across the three forms of therapy described.

The patient data set
The patient data set used for the modelling is a longitudinal data set that contains follow-up data for a cohort of 539 stroke patients, consecutively identified over a 6-month period in 1996, on stroke registers in two hospitals. Data were collected on admission, at discharge, and at 3 and 6 months, and subsequently 1, 2, and 3 years post-stroke. The data collected in hospital included admission and discharge dates, basic demographics, stroke characteristics and scan results. At each follow-up time patient status (alive or dead) was identified, and data were collected regarding residence, function, social service input, therapy input and aids provided. These patients received usual stroke care and their 3-year data were used as the baseline from which to judge the potential impact of RFTP. The baseline characteristics of these patients can be seen in Appendix 7. The characteristics of the data set compare favourably with the characteristics of the patients in the included studies.

Assumptions about health outcomes
The Barthel Activities of Daily Living Index (BI) at 3 years post-stroke was used to define outcome groups, which represented a range of disability...
levels, and such that there were similar numbers in each group. The choice of the BI was based on its widespread usage as a global outcome in stroke research and because it had been mapped onto the EuroQol-5 Dimensions (EQ-5D). The BI is a ten-item scale ranging from 0 (dependent on others for ADLs) to 20 (independent of others for ADLs); the items measured include mobility, transfers, grooming and feeding. The number of patients in each Barthel category was 28 (BI ≤ 10); 34 (BI = 11–14); 33 (BI = 15–17), 25 (BI = 18 or 19) and 30 (BI = 20).

**Efficacy of RFTP**
A range of different outcome measures was used in the systematic review. For each outcome the effectiveness of RFTP was expressed as the SMD with associated 95% CI. The exception to this was for walking distance, which was expressed as WMD. However, for the economic analysis, the SMD will be used. In the economic analysis the focus was on those outcomes that showed a significant benefit of RFTP and where there were at least 250 patients in the analysis of efficacy, because the estimates based on such a sample size would be more robust. However, walking speed was not included in the economic analysis because it was felt that walking distance was the more meaningful of these two outcomes. To determine the potential impact of RFTP, it was necessary to estimate how a change in the SMD would equate to a change on the BI. It was estimated that a change in the SMD of 0.2 was equivalent to a change in 1 point on the BI. This was based on the following assumption: SMD = (treatment mean – control mean)/SD; a ‘typical SD’ for the BI in a rehabilitation stroke population might be 5 units; therefore, an SMD of 0.2 would be 1 Barthel unit.

**Patient values preferences**
A study was identified that examined the association between the BI and the EQ-5D. Although this study was based in The Netherlands, the characteristics of the patients included in the study are similar to the characteristics of those in the present patient data set (at 6 months). The study suggested that 1 point on the BI was equivalent to 0.05 of a QALY.

**Cost**
The cost estimates reflect 2005/06 prices. Direct costs have been used, valued from an NHS public-sector perspective. The majority of the costs were obtained from national figures. The exception to this was the cost for aids, which were obtained from an NHS loan store. The assumptions made about the costs for the RFTP studies are detailed below.

**Assumptions about costing**

**Patient data set**
The analysis focused on the costs that were likely to be influenced by RFTP, which included the cost of services, therapy and aids post-discharge. Costs were estimated from the following inputs: home care, meals on wheels, chiropody, physiotherapy, occupational therapy, day centre, day hospital, wheelchair, walking frame, walking stick, toilet seat raiser, chair raiser, bed raiser, toilet frame, trolley and shopping trolley. The costs that were not included were GP attendance, readmission to hospital, clinic attendance or medication. Also excluded were hospital costs for the index stroke and subsequent hotel costs for residence in institutions. Although RFTP is likely to promote independence in everyday activities, it is unlikely that it would prevent admission to institutions. Moreover, there was some concern that high hotel costs of institutions, or even readmissions to hospital, would unduly influence the model and the authors wished to adopt a conservative approach to the estimates of cost-effectiveness.

**RFTP studies**
The RFTP studies included in the review exhibited some diversity in when and where they were performed; some were more than 10 years old and many were not based in the UK. To estimate the costs of such studies, an assumption was made that they could be performed in a similar manner in the UK. In addition, although the studies reported on how much therapy was provided, there were no data on the impact of the training on subsequent resource use. Therefore, it was assumed that the RFTP training did not result in additional costs owing to readmission or clinic attendance, caused by patients’ conditions worsening.

Because of the diverse nature of studies and the data reported therein, a somewhat pragmatic approach to costing methodology was taken. It was assumed that for all studies the therapy staff cost was £40 per hour and that as well as the cost of providing the therapy there would be an additional 20 hours of staff training per study. The lack of CIMT data from the UK meant that an estimate of the cost of CIMT equipment had to be made, of £100 per patient. The TM studies used a cost of £25,000 for the equipment plus an additional £1500 for installation. Within the RTT studies there were miscellaneous costs for which the following cost estimates were made: Bon Saint Côme trunk control and retraining device £1000, videotaped instructions and telephone contacts £500, and instruction booklets £600. In one study, a Kinetron machine was used in one
workstation out of ten. The original cost of this machine was approximately £32,000. Because this device is no longer manufactured and it contributed only a small part to the RTT input, a cost of £1000 was attributed to this device. For all equipment the one-off cost of purchase was used and no assumptions were made about the lifetime of the equipment or how often it was used.

For each trial an average cost per patient was calculated based on staff time, equipment used and number of patients randomised into the trial. Subsequently, an average cost per therapy (i.e. RTT, CIMT and TM) was calculated based on the average cost for each trial and the number of trials that contributed to that therapy modality. From this calculation the estimated average cost per patient for the individual therapies was £651 for RTT, £1773 for CIMT and £1870 for TM. Further estimates were then made of the average cost per patient for combinations of therapy. To make the calculation for combinations of therapy, an average cost for all trials in the relevant therapy modalities was estimated. This resulted in an average cost per patient of £1126 for RTT and CIMT combined, and £999 for RTT and TM combined. The overall average cost per person of RFTP (i.e. RTT, CIMT and TM combined) for the base model was estimated to be £1265.

Where outcome measures reflected all forms of therapy (overall effect), the cost of the intervention was taken from the overall average cost of RFTP. Where outcome measures reflected therapy focusing on the upper limb (arm function and ADL), the cost of the intervention was taken from the average cost of RTT and CIMT. Where outcome measures reflected therapy focusing on the lower limb (walking distance, functional ambulation and sit-to-stand), the cost of the intervention was taken from the average cost of RTT and TM.

The model
Groups were identified, based on the BI at 3 years as described above. For each group the 3-year cost was estimated: the baseline cost in this analysis. It was then assumed that for an SMD of 0.2, there would be a 1-point increase per patient on the BI, that the BI scores were evenly distributed within the groups and that the effect would be maintained over 3 years. Using this assumption, the number of patients in each of the Barthel groups was re-estimated. A new (3-year) cost was then calculated based on the new numbers in each of the groups. The difference between the baseline cost and the new cost was considered to represent the impact of RFTP on cost. An average cost per patient, reflecting the potential cost saving of RFTP, was subsequently calculated, as £47,523/150 = £316.82 (Appendix 8).

Adjustment for timing of costs and benefits
For the base model the cost-utility of RFTP over 3 years was assessed, and costs and effects were discounted at an annual rate of 3.5%.

Allowances for uncertainty
Several sensitivity analyses were performed to explore the impact of varying certain parameters on the base model:

- RFTP efficacy
- association between the SMD and the BI
- association between the BI and the EQ-5D
- cost of therapy
- discount rates.

The relationship between the cost of RFTP per patient and the cost per QALY was also explored.

Results
From the systematic review, the overall effect size for RFTP was SMD 0.34 (95% CI 0.19 to 0.48). The following outcomes were based on studies where the combined sample size was more than 250 patients, and revealed a significant effect of RFTP:

- arm function: SMD 0.24 (95% CI 0.06 to 0.42)
- ADL: SMD 0.30 (95% CI 0.09 to 0.52)
- walking distance: SMD 0.45 (95% CI 0.20 to 0.70)
- functional ambulation: SMD 0.28 (95% CI 0.05 to 0.51)
- sit-to-stand: SMD 0.39 (95% CI 0.18 to 0.61).

The effect sizes for the five outcomes are based on RTT plus one of either CIMT or TM. For arm function there was heterogeneity of effect between RTT, which was non significant (SMD 0.17, 95% CI –0.03 to 0.36) and CIMT, which was significant (SMD 0.77, 95% CI 0.26 to 1.29). However, the estimates of cost-effectiveness will use the combined effect size.

Cost-effectiveness at 3 years
In the base-case analysis using the overall effect size, the incremental cost-effectiveness ratio
(ICER) of RFTP was £10,870. Considering the efficacy and cost data for the outcome of arm function, the cost per QALY gained was £15,185 and when focusing on the efficacy and cost data for ADLs the cost per QALY gained was £11,009. Based on efficacy and cost data for walking distance the cost per QALY gained was £41,187, and for functional ambulation and sit-to-stand the cost per QALY gained was £10,187 and £5708, respectively. An intervention with an ICER of less than £20,000 is considered cost-effective (although interventions with an ICER of up to £30,000 may be considered cost-effective). Therefore, for all outcomes listed, the base analysis suggests that RFTP is cost-effective. Moreover, for walking distance and sit-to-stand, when the ICER was calculated using the lower limit of effectiveness from the 95% CI, both of the ICER values were less than £20,000 (Appendix 9; Analysis 1).

Varying the association between the SMD and the BI
If a unit change of the SMD was related to a smaller change on the BI, the cost per QALY gained increases for all outcome measures. In the base case the ratio of SMD to BI is 1:5. Even if this ratio is changed to 1:4, the ICER remains below £20,000 per QALY gained for all outcomes except for arm function (£20,405). Sit-to-stand remains cost-effective at a ratio of 1:3 and walking distance remains cost-effective at a ratio of 1:2 (Appendix 9; Analysis 2).

Varying the association between the BI and the EQ-5D
If a unit change on the BI is associated with a smaller change in the EQ-5D the ICER increases for all outcome measures. If a change in 1 point on the BI is equivalent to only 0.04 of a QALY, all outcomes continue to suggest that RFTP is cost-effective (Appendix 9; Analysis 3).

Varying therapy cost
RFTP remains cost-effective on all outcomes except for arm function if the cost of therapy per hour is increased to £60. However, RFTP is marginally cost-effective for arm function if the cost of therapy rises to £50 per hour (Appendix 9; Analysis 4).

Varying discount rate (cost)
If the discount rate for costs is reduced from 3.5% to 0% then the ICER is reduced to £10,228 for the overall outcome and, for example, £3545 for walking distance and £14,543 for arm function. If the discount rate for cost is increased from 3.5% to 6%, RFTP is cost-effective on all outcomes (Appendix 9; Analysis 5).

Varying discount rate (outcome)
If outcome is not discounted then the ICER is reduced to £9191 for the overall outcome and, for example, £3186 for walking distance and £13,068 for arm function. Even if the discount rate is increased to 6%, RFTP is cost-effective on all outcomes (Appendix 9; Analysis 6).

Varying the association between the BI and the EQ-5D
If a unit change on the BI is associated with a smaller change in the EQ-5D the ICER increases for all outcome measures. If a change in 1 point on the BI is equivalent to only 0.04 of a QALY, all outcomes continue to suggest that RFTP is cost-effective (Appendix 9; Analysis 3).

Varying therapy cost
RFTP remains cost-effective on all outcomes except for arm function if the cost of therapy per hour is increased to £60. However, RFTP is marginally cost-effective for arm function if the cost of therapy rises to £50 per hour (Appendix 9; Analysis 4).

Varying discount rate (cost)
If the discount rate for costs is reduced from 3.5% to 0% then the ICER is reduced to £10,228 for the overall outcome and, for example, £3545 for walking distance and £14,543 for arm function. If the discount rate for cost is increased from 3.5% to 6%, RFTP is cost-effective on all outcomes (Appendix 9; Analysis 5).

Varying discount rate (outcome)
If outcome is not discounted then the ICER is reduced to £9191 for the overall outcome and, for example, £3186 for walking distance and £13,068 for arm function. Even if the discount rate is increased to 6%, RFTP is cost-effective on all outcomes (Appendix 9; Analysis 6).

**FIGURE 30** Impact of varying the cost of RFTP on the cost per QALY gained
Association between cost of RFTP and cost per QALY gained
The base costs were used to calculate how a change in the cost of RFTP per patient affects the ICER per QALY gained. At an ICER of £20,000 per QALY gained the average cost of RFTP per patient is £1963, which approximates to 49 hours’ contact per patient, excluding equipment costs (Figure 30).

## Chapter 6

### Discussion

**Summary of main results**

**Upper limb function/sitting balance**

In total, 19 RFTP trials with 634 participants measured arm or hand function. Eight were RTT trials with 467 participants. Of these, two trials were whole therapy approaches, two trials were circuit-training approaches, three trials were functional task practice mixed in with other forms of upper limb exercise, and one trial was the intensive practice component of constraint-induced movement therapy, without the constraint. All of these interventions were delivered by a therapist, except for one trial, which consisted of self-initiated practice in the home environment, using a booklet of exercises, after instruction by a therapist. Of the upper limb training trials, all but two were carried out 0–6 months post-stroke. Five trials had a total training time of 20 hours or less, and three trials provided more than 20 hours’ total training time. In two of the trials training time was additional. All eight trials with eight intervention–control pairs relevant to this review provided data suitable for pooling.

Eleven of the 19 trials measuring arm or hand function were CIMT trials with 190 participants. Of these, five trials were of constraint-induced therapy, and six trials were of modified constraint-induced therapy. All of the interventions were delivered by a therapist, in one-to-one therapy. Three trials recruited within 14 days post-stroke, four trials recruited between 15 days and 6 months post-stroke, and four trials recruited after more than 6 months post-stroke. All but two trials had a total training time of over 20 hours, with the majority providing between 30 and 60 hours' training. In four trials, training time was additional to the amount of training time provided to the comparison group, while in one trial it was unclear whether training time between experimental and comparison groups was equivalent. Eight CIMT trials including 151 participants in eight intervention–control pairs relevant to this review provided data suitable for pooling. Pooled results show evidence of a small effect (SMD 0.24, 95% CI 0.06 to 0.42).

Seven RFTP trials with 357 participants measured hand function. There was no statistically significant pooled effect (SMD 0.19, 95% CI –0.03 to 0.42).

Five trials (all RTT) with 256 participants measured sitting balance/reach from sitting. Of these, two trials were whole therapy approaches, while the other three trials specifically trained sitting balance or reach from sitting. All of the interventions were carried out in the 0–6-month post-stroke period and were delivered by a therapist in a hospital setting, except for one trial where the intervention was carried out at home, with people more than 6 months post-stroke. All of the interventions were 20 hours’ training or less. There was no evidence for impact on sitting balance/reach (SMD 0.23, 95% CI –0.05 to 0.50).

Results at follow-up for all upper limb trials to 6 months post-therapy were moderate and statistically significant (SMD 0.55, 95% CI 0.06 to 1.04). Evidence for a retention effect at more than 6 months post-therapy was unclear (SMD –0.02 to 95% CI –0.31 to 0.26), as it was noted that the trials with 6–12-month follow-up also showed little or no effect post-treatment.

Treatment effects for upper limb interventions were not modified by amount/dosage of task practice or time since stroke, but were modified by type of intervention, with RTT showing a small effect size just failing to reach significance (SMD 0.17, 95% CI –0.03 to 0.36), and CIMT showing a large, statistically significant effect (SMD 0.77, 95% CI 0.26 to 1.29). However, tests for the effect of quality of allocation concealment and trial size were also significant, with all of the CIMT trials in both the inadequate/unclear allocation concealment subgroup and the small trials subgroup. This suggests that the results for CIMT trials could be influenced by quality issues and reporting bias.

**Lower limb function/standing balance**

Seventeen RFTP trials with 747 participants measured some aspect of lower limb function or standing balance/reach. Eleven were RTT trials with 531 participants. Of these, one trial...
specifically trained sit-to-stand movements, three trials trained balance, two trials were whole therapy approaches, three trials were circuit-training approaches, and two trials were lower limb task practice mixed in with other forms of mobility exercise. All interventions were delivered by a therapist in a hospital or community setting, except for one trial, which was a home mobility programme, where the participant followed videotaped exercise with therapist telephone contact and follow-up. Three of the interventions were carried out more than 6 months post-stroke. All 11 trials had data suitable for pooling. Six of the 17 trials were TM trials with 229 participants. Of these, two trials were of unsupported TM and four trials were of bodyweight supported TM. All interventions were delivered by a therapist in a hospital setting. Two interventions were carried out more than 6 months post-stroke. Only one of the trials included more than 20 hours’ training time. Five trials with 199 participants provided data suitable for pooling.

Results show large statistically significant effects for walking distance (WMD 50.05 m, 95% CI 29.65 to 70.44 m; SMD 0.98, 95% CI 0.58 to 1.39). In effect, participants in the experimental groups could walk on average 50 m further in 6 minutes than the control groups. There was some heterogeneity of treatment effects for walking distance. There were also small statistically significant effects for walking speed (SMD 0.28, 95% CI 0.09 to 0.47) and functional ambulation (SMD 0.28, 95% CI 0.05 to 0.51). Trials of RTT showed a small to moderate effect on sit-to-stand (standardised effect size 0.39, 95% CI 0.18 to 0.61), but no evidence of effect on lower limb function measures (SMD 0.20, 95% CI –0.10 to 0.50) or standing balance/reach (SMD 0.29, 95% CI, –0.06 to 0.63).

Retention effects on lower limbs were small to moderate and statistically significant up to 6 months post-therapy (SMD 0.37, 95% CI 0.05 to 0.69), but there was no evidence of an effect at later than 6 months (SMD –0.01, 95% CI –0.32 to 0.29). This difference in retention effects was borderline statistically significant ($p = 0.09$). However, few trials had long follow-up and those that did tended to show little or no effect post-treatment. Findings are also quite heterogeneous, which suggests that they are inconclusive.

Treatment effects were not modified by amount of task practice, time since stroke or type of intervention. Tests for the effect of quality of allocation concealment were not statistically significant. However, trials with high (>20%) loss to follow-up showed a significantly lower effect of RTFT than did trials with lower (≤20%) loss. This is an indication that any bias due to very high dropout is not in favour of RTT, although it would be important in future trials to try to characterise dropouts and attempt to determine their effect on the effectiveness of RTFT. There was some indication that treatment effects might be modified by type of comparison group ($p = 0.10$), with usual care or alternative treatment comparisons showing a smaller treatment effect than attention-control or no-treatment comparisons. This suggests that type of comparison group should be taken into consideration in future analyses.

Global motor function

Two RTT trials and one TM trial with data suitable for pooling recruiting 242 participants in total measured global motor function. Data were available for 76% ($n = 183$). There was a pooled small to moderate, statistically significant effect (SMD 0.38, 95% CI 0.09 to 0.68).

ADL function

Five RTT trials and one CIMT trial recruiting a total of 422 participants used an ADL measure. Outcome data were available for 83% ($n = 345$). Overall results indicated a small effect size that was statistically significant (SMD 0.30, 95% CI 0.09 to 0.52).

Adverse events

Ten out of the 31 trials included some report of adverse events. Of these, seven reported no adverse events. One RTT trial reported a number of falls occurring during the intervention or evaluation, none of which was serious, and one CIMT trial reported that three participants had some discomfort in the unaffected limb, attributed to overuse during the constraint period. The protocol was subsequently modified. The only trial formally to measure adverse events did not show any significant difference in fall rates between the intervention and control groups.

Overall completeness and applicability of evidence

The included trials were clinically diverse in terms of timing and focus, and there are gaps in the evidence base, particularly for people more than 6 months post-stroke. Of the five trials that
evaluated more than 20 hours’ therapy for upper limbs in this participant group, only three had usable data.\textsuperscript{52-74} Only one trial evaluated 20 hours or less of upper limb therapy in people at least 6 months post-stroke.\textsuperscript{32}

There were only three trials that evaluated up to 20 hours of lower limb therapy in people more than 6 months post-stroke,\textsuperscript{51,67,87} and two trials evaluating more than 20 hours of lower limb therapy in this group.\textsuperscript{78,88}

There have been more trials undertaken with people in the 0–6-month post-stroke period, but here there are also gaps in the evidence base. Of the seven trials evaluating upper limb therapy of more than 20 hours’ duration, one had data unsuitable for pooling. Of the remaining six, one was quasi-experimental, and three had ten participants or fewer. While 11 trials have evaluated 20 hours or less of lower limb therapy, only one trial has evaluated more than 20 hours of lower limb therapy in the 0–6-month post-stroke period.

Although it was not possible to classify studies into more disabled or less disabled participant subgroups, the tables of included studies (Appendices 1–3) illustrate the wide range of disability levels of the participants in the included trials. However, many of the trials had inclusion criteria specifying either minimum, or minimum and maximum levels of ability, motivation to participate and ability to understand instruction. The general evidence provided by the review therefore appears to be widely applicable, perhaps with the exception of very severely disabled people with little postural control or voluntary movement, those with very mild deficits and those with severe communication difficulties who were excluded by trialists. The exception to the above may be in CIMT studies, which identified criteria for minimum levels of finger and wrist extension. Treatment effects for CIMT may only be applicable to a subgroup of participants with a degree of voluntary movement in the hand or arm. There is also the possibility that exclusion criteria for maximum residual ability reduce generalisability. The preliminary phase of a CIMT trial reported that less than 5% of stroke admissions qualified for randomisation.\textsuperscript{84}

Trials were excluded where repetition appeared to be primarily for strength or endurance training (e.g. cycling and gait training), or where the type of training appeared divorced from the functional aim (e.g. backward walking training, slot machines and computer games). This may have consequences for the applicability of the evidence. The exclusion of trials of what could be defined as ‘prefunctional’ types of movement will effectively have excluded a group of people who cannot yet participate in functional movement. The same consequence applies to the exclusion of trials with a large element of passive and active assisted movement.

In terms of generalisability to the UK, only RTT-type interventions have been evaluated in this setting. One trial is a whole therapy approach,\textsuperscript{70} one trial evaluates balance training\textsuperscript{77} and one quasi-experimental trial evaluated self-delivered exercise in the home environment.\textsuperscript{59} RTT has not traditionally been a significant part of therapy after stroke in the UK, which has been dominated by the Bobath approach. This specifically minimises repetitive active movement, and relies on therapist-guided restoration of ‘normal movement’ patterns, rather than the functional but unnatural ones that could occur as a result of the more pragmatic approach within RFTP. Many studies in this review were from outside the UK, or used therapy approaches that have been less popular, such as motor learning. While clinical experience suggests that modern UK stroke units have a more eclectic therapy approach, it may take longer for the results to change practice within the UK than in countries that already use RFTP routinely.

There are no published trials of either CIMT or TM in a UK setting. While all of the interventions are likely to be transferable in principle, their effectiveness against other forms of care usual in the UK and their acceptability in this healthcare setting have not been tested. In particular, the feasibility and acceptability of CIMT and circuit-training interventions delivered in community settings would need to be evaluated. The intensity of CIMT and the delivery of interventions after the normal rehabilitation period represent additional periods of treatment to those currently provided.

The acceptability and safety of the different forms of RFTP to all types of participants are also unclear. While there were few adverse effects reported overall, the lack of formal reporting in many trials means that this finding is inconclusive. Of the information provided about reasons for dropouts in the trials, the most frequent cause was physical illness, and only a very small proportion of those participating dropped out for physical reasons that might have been related to the intervention. However, there was also a small
number of participants who were lost to follow-up for reasons related to compliance or treatment preference. In the CIMT trials in particular, relatively long periods of constraint and intensive periods of practice with the affected limb have the potential to impact on acceptability, although none of the trials reported problems.

Information about recruitment was not often provided, but of those that did provide information, a trial recruiting in hospital in the early rehabilitation period had relatively low numbers of refusal to participate (e.g. Kwakkel53 had four out of 101 people who did not give consent), while a trial recruiting in the community after rehabilitation had high numbers of refusal of the intervention (e.g. Salbach51 had 73% refusal). It may be that some forms of intervention are less acceptable, or that interventions only appeal to a subset of stroke survivors, particularly if travel is involved.

No conclusions could be reached about the impact of numbers of repetitions as a measure of the intensity of practice, as this information was only provided in one or two trials. The amount of task practice is therefore a measure of the duration (i.e. time spent).

By virtue of its focus on functional movement, this review does not consider the evidence for electronic forms of delivery of repetitive movement such as robotics or computer-mediated practice. The authors were also unable to comment on the implications of different sites of treatment, therapist-delivered versus self-delivered interventions or group versus individual delivery, as there were too few trials for comparison. However, the presence of two trials involving self-delivery in the home environment and four trials involving group delivery of task-specific training suggests that these modes of delivery are feasible, and further ongoing trials should provide more information. The studies that collected information showed generally high levels of satisfaction with the programme. Attendance levels at community programmes were also very good, suggesting that training programmes were well received by those who chose to participate.

**Quality of evidence**

For lower limb trials, Salbach and colleagues51 estimate that a sample size of 60 would be required to detect a group difference of 28 m in average change in the 6WMT (type I error = 0.05, type II error = 0.10, expected dropout rate of 10%) based on the results of a pilot study67 which recruited 91 patients. Five of the 17 trials of lower limb interventions had sample sizes above 60 (four RTT, one TM). For upper limb trials, the same research group estimated that a sample size of 60 participants was required to detect a clinically meaningful difference for the BBT.32 Of the 19 trials of upper limb interventions, five trials had sample sizes greater than 60 (five RTT). No CIMT trial had more than 25 participants.

Two-thirds of RTT trials had adequate allocation concealment and most of the trials stated that blinded independent assessors were used. Therapy time was non-equivalent in two trials. For TM, two out of five trials with data included in the meta-analysis described adequate allocation concealment methods, blinding of outcome assessors was attempted in three trials, and all trials provided equivalent therapy time to experimental and comparison groups. Only four trials (two RTT, one CIMT, one TM) had over 20% dropout. For CIMT, three trials provided data unsuitable for pooling; and all of the CIMT trials had unclear allocation concealment.

The overall quality of the included trials provides a degree of confidence in the pooled results for RTT and TM, although there were only five TM trials with data suitable for pooling from 199 participants. The results for CIMT have to be considered in the light of small size of the trials, together with the confounding effects of the selection of trials with non-equivalent therapy time in the experimental and control groups (i.e. no-treatment control groups). A number of CIMT trials did include comparison groups who received therapy with no constraint, but these were intervention–control pairs that could not be used for this review as the comparison was also repetitive task practice. The use of no-treatment control comparison may lead to a different conclusion from other reviews of CIMT. Three out of eight included CIMT trials compared the intervention against no therapy. This may explain the large effect of the intervention on upper limb function, as the differential between these groups may be larger than would be expected by comparing the intervention against usual care or another intervention, such as bimanual training.

Non-reporting bias also has to be considered. Subgroup analysis for trial size and the funnel plot for upper limb interventions suggested greater effects for smaller trials, suggesting an absence of small, negative trials. This might have led to small or negative effect estimates not being included.
and, in particular, an ‘unbalancing’ due to the four trials with large effects.

Potential limitations in the review process

This review combined the results of trials of RTT with results from trials of enhanced forms of RTT, namely TM and CIMT. Care must therefore be taken regarding attribution of pooled treatment effects solely to the task practice component. For this reason, both separate and pooled results are shown. This study also generally used fixed-effect analyses, which some might criticise owing to the presence of some clinical heterogeneity in the treatments and trials combined. Many of the trials originally reported data in median and interquartile ranges. In addition, many of the outcomes are measured on scales that are short and bounded, where the use of means and standard deviations can be misleading. However, the effect size for RFTP is greatest for walking distance, which is a truly quantitative measure. It is also relatively consistent across other outcomes, including walking speed which is, like walking distance, a continuous measure with essentially no strict upper bound. This would tend to indicate that the use of means and standard deviations for short, bounded, ordinal scales has not substantively affected the conclusions, at least for the lower limb outcomes.

The major focus in this review was impact on task-specific function. In practice, a large number of studies was excluded on the basis that the reviewers did not judge the outcomes to be functional or the intervention to be task specific. Studies were also included where the reviewers’ interpretation of the intervention was that repetition of functional movement was a major mechanism of action, even if this was not explicitly stated by the authors (e.g. de Sèze). Whether balance training is truly ‘functional’ is also a matter of interpretation, but its inclusion was felt to be important so as not unintentionally to exclude RFTP training for people with more severe levels of disability, where the recovery of balance is a prerequisite of functional activity.

As CIMT and TM trials were sourced from existing reviews, trials with alternative or no-treatment comparisons were included. Two TM trials included comparisons against alternative forms of treatment, which is potentially likely to have resulted in lower estimates of effect than comparison against usual care; subgroup analysis for type of comparison group was close to statistical significance, with a lower effect estimate for the usual care/alternative treatment than for the attention-control/no-treatment comparison subgroup. Three CIMT trials included comparison against a no-treatment group, with the potential to result in greater estimates of effect than comparison against usual care. However, analysis of the impact of comparison group provided no evidence of any difference between the effects in the two subgroups.

Agreement or disagreement with previous reviews

All of the studies included in this review have a core component of repeated, task-specific practice, but they are also very diverse. The CIMT and TM components of the review were subsets of existing reviews. While combining the results from such a diverse group of studies has potential dangers, the summary finding of a pooled moderate impact on functional ability (SMD 0.34, 95% CI 0.19 to 0.48) supports previous authors who have suggested a focus on the efficacy of task-specific treatments.

Whether functional gain can be attributed to task specificity or repeated practice is unclear and any attribution is highly speculative. This review did not find a significant difference in treatment effect dependent on the amount of practice for lower limb interventions. Conversely, the greatest gains for lower limbs were seen in walking distance, while gains for walking speed were of a smaller magnitude, suggesting that an endurance training element contained in repeated motor practice makes some contribution to impact. In addition, this review could not take into account the pretherapy ability levels of the participants, and it may also be that the mechanisms of repetition and task specificity have different roles at different stages of recovery. Repetition is the major mechanism of action of robotics, and a recent review has shown impact at the level of impairment, but not for functional ability.

For upper limb interventions, five out of eight CIMT studies with data suitable for pooling provided more than 20 hours of therapy. Although the overall difference between smaller and larger amounts of task practice was not statistically significant, there was potential evidence of a trend (p = 0.18) towards larger effect sizes for more than 20 hours’ practice (SMD 0.42, 95% CI 0.10 to 0.75) versus 0–20 hours’ practice (SMD 0.22,
95% CI –0.12 to 0.57) for arm function. This finding is consistent with other reviews that have suggested that upper limb recovery may require intensive intervention. Overall for RFTP, there were small to moderate effects for ADLs and global motor function, and a small effect on functional ambulation classification. Even though the amount of change for these outcomes is modest, the clinical benefits are likely to be meaningful in relation to quality of life.

In those studies that did show a benefit and provided later assessments, improvements at the end of training were not evident at the later stage. It is unclear from this review whether this is related to characteristics of the participants, the intensity of training or the degree of improvement required before detectable change was noted.

Evidence from RFTP interventions does not concur with the suggestion that earlier provision of treatment results in greater functional improvement, as treatment effects were not modified by time since stroke. Improvement in function was possible even in the later stages of recovery. A recent review concluded that it was surprising that CIMT should work in the chronic phase of stroke, but agreed that the trial and laboratory evidence suggested that this was the case. However, they concluded that teaching bimanual activities rather than constraint might create the same outcome.

The authors were unable to come to any conclusions about the previously identified dose–response relationship between amount of therapy and improved outcome, but the results from subgroup analysis suggest this as a priority for further research.

**Economic analysis**

The base-case analysis suggested that RFTP is cost-effective. This analysis is based on a number of assumptions about therapeutic inputs that had to be made because of the paucity of economic data associated with the individual trials. Furthermore, in calculating cost-effectiveness the authors had to estimate the potential impact of RFTP on pre-existing longitudinal data. To allow for these assumptions their magnitude was varied in sensitivity analysis. The sensitivity analyses tended to find that RFTP was cost-effective overall, and in particular on the outcome measures of walking distance and sit-to-stand.

The existing data set used to estimate the impact of RFTP was appropriate to the study’s needs because it reflected the normal course of recovery after stroke in a cohort of patients that had been systematically identified. The disadvantage of using this data set was that the analysis was based around predetermined data, which did not specifically lend itself to assessing the impact of RFTP. However, the existing data did allow reasonable assumptions to be made about how RFTP may have affected outcomes and costs, and meant that the research team did not have to wait for 3 years to collect data on resource use and outcomes in a UK post-stroke population.

One of the costs from the existing data set that could have been included was the cost incurred through residence in institutions. These costs tend to be high and would most likely be important in patients with more severe disability. Not including the cost of residence in institutions means that the costs of these severe states are likely to have been underestimated. Evidence from this review suggested that RFTP reduced disability. Therefore, by excluding the high severe state costs due to institutionalisation, the review is likely to have underestimated the potential savings and consequently the cost-effectiveness of RFTP.

Translation of the potential effect of RFTP on the patients in the data set made an assumption about the relationship between the effect size and the BI. This assumption was based around the size of the standard deviation in rehabilitation trials. The assumption that the standard deviation was about 5 is consistent with published data. Furthermore, in this systematic review the effect of RFTP on ADLs resulted in an SMD of 0.30. This would suggest that the assumption about the relationship between the SMD and the BI was, if anything, a conservative one, therefore, it is likely that the cost-effectiveness of RFTP has been underestimated.

A further assumption was then made about the relationship between the BI and the EQ-5D. This assumption allowed the calculation of ICER per QALY gained. The systematic review showed that none of the studies used the EQ-5D and only one used a measure of quality of life (not including health status) as an outcome. It therefore seemed unreasonable to generate an effect size for quality of life, based on one study. Consequently, this makes it difficult to compare directly the relationship between RFTP and quality of life, and suggests that future RFTP studies should use a quality of life measure as an outcome.
To test the assumptions that were made about the relationships between the effect size, the BI and QALYs, sensitivity analyses were performed. These analyses explored what would happen if the impact of RFTP on outcome was less than in the base model. For the assumptions made, the cost per QALY gained was more sensitive to variations between the effect size and the BI than to variations between the BI and the EQ-5D. Overall, the cost per QALY gained for walking distance did not rise much above £20,000, except for one of the assumptions made in the sensitivity analysis. This means that even when the assumptions are stacked against RFTP, this intervention still demonstrates cost-effectiveness.

The estimation of the cost of providing RFTP in the trials was complicated for a number of reasons. Many of the trials were not conducted in the UK, so it was difficult to cost some items of equipment. The grade of staff performing the training was not often reported; this was further compounded by the trials not being UK based. In addition, because the individual trials had not specifically recorded resource-use data, no information was available about the impact of RFTP on future therapy, support services or provision of mobility aids. Moreover, there were no consistent data about adverse events, which would have the potential to increase costs through patients attending clinics or being admitted to hospital. In one study87 some patients were transported to hospital at the expense of the researcher; for all other studies post discharge, patients made their own way to clinics. It is likely that this cost was incurred because the intervention was being used in the context of a research study rather than normal clinical practice. Furthermore, if RFTP was introduced as a rehabilitation therapy it is unlikely that it would incur major direct costs for patient transport. For this reason the cost of this transport was not included as a source of cost for RFTP. Given the lack of associated economic data, the costing of RFTP was a fair reflection of the direct costs incurred by this intervention.

The systematic review revealed the complex nature of RFTP in terms of what is being delivered as well as when (after stroke), where and how it is delivered. This provided a challenge for modelling the cost-effectiveness of this intervention. It was therefore decided that rather than develop a complex model, the modelling should be kept simple and transparent. As a result of this decision the reviewers considered how RFTP might influence 3-year costs by looking at the potential impact on the 3-year BI. It is self-evident that to have a 3-year BI a patient must be alive; this meant that the estimate did not take into account the possibility that a patient who had RFTP died within the 3-year period, which may have impacted on the cost. A further analysis was subsequently performed that examined how the impact of RFTP on the 3-month BI would affect cost at 3 years, i.e. this analysis included people alive at 3 months, some of whom had died by 3 years. It was found that the magnitude of the potential cost saving was similar whether the 3-month or 3-year BI scores were used.

To make the modelling feasible a number of other assumptions had to be made. The costing of usual care went from discharge to 3 years post-stroke, which makes the assumption that the cost over 3 years would be the same whenever RFTP was started. Another related assumption was that the effect of RFTP is constant over time. It is acknowledged that these assumptions are rather general. However, given the complex nature of the intervention, described in the previous paragraph, and the lack of economic data about the intervention and its likely impact on cost, the authors believe that these assumptions provided a reasonable estimate.

In summary, the systematic review was able to combine the results from different studies and provide an overall effect size for RFTP. The lack of economic data associated with the existing studies meant that an economic model had to be developed to estimate the potential cost-effectiveness of RFTP. The modelling had the advantage of using effect sizes from a large sample; the disadvantage was that it relied on pre-existing data. This meant that the modelling that was performed relied on a number of assumptions about costs and effectiveness. The assumptions that were made were generally weighted against RFTP. Despite these assumptions, RFTP demonstrated that it was cost-effective.

To combat the issues around measures of costs and effectiveness, future trials need to be sufficiently powered to detect the effectiveness of both functional and economic outcomes. Furthermore, trials need to decide a priori what resources to cost; because the effects of RFTP are likely to extend beyond its impact on direct costs future trials should also consider indirect and possibly intangible costs. Economic analysis would be facilitated further by including quality of life as an outcome measure.
Implications for practice

The results of this review provide sufficient evidence to validate the general principle that RFTP for lower limbs can result in functional gain, when compared against other forms of usual care or attention-control. While functional gain overall is modest, impact does appear to be of a clinically meaningful magnitude. It is, however, unclear as to whether effects are sustained over 6 months post-therapy.

There is insufficient evidence to make any recommendations for upper limb interventions. Although effects of RFTP on arm function were statistically significant, the variable quality of the evidence and the clinical heterogeneity of the interventions mean that further research is needed before specific recommendations can be made.

Some caution is needed in interpreting the lack of evidence for adverse effects, as few trials specifically monitored these as an outcome. If task-specific training is used in clinical practice, adverse effects should be monitored.

While the overall effectiveness of RFTP is relatively modest, this sort of intervention appears to be cost-effective, primarily because the intervention itself has a relatively small cost.

Recommendations for future research

There is a large number of ongoing trials in this area. The first recommendation is that this review is updated within 2 years. The updated review should also consider any potential interaction effects between type of training, amount of task practice and stroke-related impairments. This review focused initially on the evidence for the efficacy of RFTP versus usual care or attention-control comparisons. Any future review should include comparison of RFTP against alternative forms of therapy, such as strength and stamina training.

Further well-designed, adequately powered trials evaluating the impact of upper limb interventions, and in particular CIMT, are needed. One trial was published shortly after the closing date for this review, and should provide more information on efficacy. Future CIMT trials should also target and measure hand function.

There were insufficient trials included in this review to evaluate the efficacy and cost-effectiveness of different intervention delivery methods for RFTP, such as group training, delivery by assistants or practice in the home environment. Further research should address practical and cost-effective ways of delivering such interventions. In particular, the acceptability of CIMT and of circuit-training-type interventions delivered in community settings would need to be evaluated.

The existence of retention effects up to 6 months post-therapy is a promising finding, and further research should be directed towards evaluating long-term functional gain by routine inclusion of longer follow-up periods of 1 or possibly 2 years. Suitable methods to maintain functional gain should also be investigated.

Future trials need to be designed to take account of the following:

- This study was unable to investigate the impact of training on people with different levels of pre-intervention disability, because of the wide range of baseline measures used. Analyses of this type would be facilitated by the inclusion in trials of baseline data using a common measure such as the BI, which can be related to population norms dependent on time since stroke.
- Monitoring and reporting of adverse effects should be explicitly included.
- When designing future trials of any type of RFTP it is critical that the study is powered to detect not only a clinical effect, but also whether it is cost-effective.
- Future studies need to identify clearly which resources are likely to be affected by RFTP and ensure that they are included in any economic analysis. In addition, studies should include a quality of life measure as one of the outcomes to facilitate economic analysis.
- The benefit of RFTP may not be clear from direct costs alone; therefore, future studies should include indirect costs and give some consideration to the inclusion of intangible costs.
We wish to acknowledge the help and support of Brenda Thomas and Hazel Fraser from the Cochrane Stroke Group, for their help in the review process. We would also like to thank all of the trial authors who kindly replied to our requests for information, and our translators: Jie Shen, Dr Qinghai Huang, Hua Zhang, Gediminas Juaga and Luyan Fang.

Contribution of authors
Beverley French (Senior Research Fellow, University of Central Lancashire) led the systematic review, including coordinating the review process, managing searching and main data input and drafting the final report. Michael Leathley (Postdoctoral Research Fellow, University of Central Lancashire) led the cost-effectiveness component of the review, and contributed to data extraction and appraisal for the review. Christopher Sutton (Senior Lecturer, University of Central Lancashire) provided statistical expertise to the review and cost-effectiveness analysis. Joanna McAdam (Research Coordinator, University of Central Lancashire) managed the TM component of the review, was responsible for administration of the review process and contributed to data extraction and appraisal and to drafting the final report. Lois Thomas (Senior Research Fellow, University of Central Lancashire) managed the CIMT component of the review and contributed to data extraction and appraisal, and to drafting the final report. Anne Forster (Reader, Elderly Care, University of Leeds), Peter Langhorne (Professor of Stroke Care, University of Glasgow) and Christopher Price (Clinical Senior Lecturer/Consultant Physician, Northumbria Healthcare NHS Trust) directed the review focus and quality, and undertook critical reading of outputs. Andrew Walker (Senior Lecturer in Health Economics, University of Glasgow) directed the focus and quality of the cost-effectiveness component of the review. Caroline Watkins (Professor of Stroke and Older People’s Care, University of Central Lancashire) was lead investigator for the project, responsible for managing the overall review process and quality of outputs.

Study details:
- Participants stratified into three groups based on comfortable walking speed. Sequence of random assignments computer generated in randomly ordered blocks of 2 and 4 for each stratum. Allocation maintained in sealed, opaque envelopes, prepared before recruitment by persons not involved in the study, and unveiled after baseline assessment and stratification.
- Inclusion criteria: First or recurrent stroke, under 1 year post-stroke at recruitment, able to walk 10 m but with residual walking deficit from most recent stroke, mental competency and ability to comprehend instructions, discharged from physical rehabilitation and resident in the community.
- Exclusion criteria: Resident in permanent care facility, co-morbidity precluding participation.
- Mean age: 72 years, (range 38–91), 61.5% male.
- Stroke details: First or recurrent stroke, 83% ischaemic, 56% right hemiparesis, 43% left hemiparesis, 1% bilateral.
- Time since stroke: mean 228 days (SD 78).
- Preintervention functional ability level: 6MWT mean 207 m (SD 128).

Outcomes:
- Limb-specific function: 6MWT, 5-m walk at comfortable and maximum speed, TUG, Berg Balance Scale, Activities Specific Balance Confidence Scale.
- Global ADL: BI.

Notes:
- 86% of mobility group subjects attended 17 or more sessions out of 18. 72% of upper extremity attended 17 or more sessions.
- 344 people were evaluated for participation but 73% refused because they could not tolerate the travel required for attendance.

Experimental intervention: Aerobic treadmill training with bodyweight either not supported or supported to a maximum of 15% using a harness. Intervention also included other individual physical therapy. Treadmill training was graded to a defined training heart rate. If necessary, one or two therapists provided help with setting the paretic limb, assisting weight shifting and hip extension. Treated as inpatients for five 60-minute sessions consisting of 30 minutes’ treadmill training and 30 minutes’ individual physical therapy per week for 6 weeks. Comparison group: Bobath-orientated individual physiotherapy exclusively concentrated on walking rehabilitation. Included tone-inhibiting and gait preparatory manoeuvres and walking practice on the floor and stairs.

\(^a\) 1, Base case; 2, varying the association between the SMD and the BI (shaded cells are base case); 3, varying the association between the BI and the EQ-5D (shaded cells are base case); 4, varying the cost per hour of client contact with therapist (shaded cells are base case); 5, varying the discount rate on cost (shaded cells are base case); 6, varying the discount rate on outcome (shaded cells are base case).

\(^b\) Cost per QALY gained, where the cost of the intervention is £1265 (based on the average cost of RTT, CIMT and TM).

\(^c\) Cost per QALY gained, where the cost of the intervention is £1126 (based on the average cost of RTT and CIMT).

\(^d\) Cost per QALY gained, where the cost of the intervention is £999 (based on the average cost of RTT and TM).
Health Technology Assessment reports published to date

**Volume 1, 1997**

No. 1
Home parenteral nutrition: a systematic review.
By Richards DM, Deeks JJ, Sheldon TA, Shaffer JL.

No. 2
Diagnosis, management and screening of early localised prostate cancer.
A review by Selley S, Donovan J, Faulkner A, Coast J, Gillatt D.

No. 3
The diagnosis, management, treatment and costs of prostate cancer in England and Wales.
A review by Chamberlain J, Melia J, Moss S, Brown J.

No. 4
Screening for fragile X syndrome.
A review by Murray J, Cuckle H, Taylor G, Hewison J.

No. 5
A review of near patient testing in primary care.

No. 6
Systematic review of outpatient services for chronic pain control.
By McQuay HJ, Moore RA, Eccleston C, Morley S, de C Williams AC.

No. 7
Neonatal screening for inborn errors of metabolism: cost, yield and outcome.

No. 8
Preschool vision screening.
A review by Snowdon SK, Stewart-Brown SL.

No. 9
Implications of socio-cultural contexts for the ethics of clinical trials.
A review by Ashcroft RE, Chadwick DW, Clark SRL, Edwards RHT, Frith L, Hutton JL.

No. 10
A critical review of the role of neonatal hearing screening in the detection of congenital hearing impairment.
By Davis A, Bamford J, Wilson I, Ramkalawan T, Forshaw M, Wright S.

**Volume 2, 1998**

No. 1
Antenatal screening for Down’s syndrome.
A review by Wald NJ, Kenward A, Hackshaw A, McGuire A.

No. 2
Screening for ovarian cancer: a systematic review.
By Bell R, Petticrew M, Luengo S, Sheldon TA.

No. 3
Consensus development methods, and their use in clinical guideline development.

No. 4
A cost-utility analysis of interferon beta for multiple sclerosis.

No. 5
Effectiveness and efficiency of methods of dialysis therapy for end-stage renal disease: systematic reviews.
By MacLeod A, Grant A, Donaldson C, Khan I, Campbell M, Daly C, et al.

No. 6
Effectiveness of hip prostheses in primary total hip replacement: a critical review of evidence and an economic model.

No. 7
Antimicrobial prophylaxis in colorectal surgery: a systematic review of randomised controlled trials.
By Song F, Glenny AM.

No. 8
Bone marrow and peripheral blood stem cell transplantation for malignancy.
A review by Johnson PWM, Simnett SJ, Sweetenham JW, Morgan GJ, Stewart LA.

No. 9
Screening for speech and language delay: a systematic review of the literature.
By Law J, Boyle J, Harris F, Harkness A, Nye C.

No. 10
By Sculpher MJ, Petticrew M, Kelland JL, Elliott RA, Holdwright DR, Buxton MJ.

No. 11
Detection, adherence and control of hypertension for the prevention of stroke: a systematic review.
By Ebrahim S.

No. 12
Postoperative analgesia and vomiting, with special reference to day-case surgery: a systematic review.
By McQuay HJ, Moore RA.

No. 13
Choosing between randomised and nonrandomised studies: a systematic review.
By Britton A, McKee M, Black N, McPherson K, Sanderson C, Bain C.

No. 14
Evaluating patient-based outcome measures for use in clinical trials.
A review by Fitzpatrick R, Davey C, Buxton MJ, Jones DR.
Vol. 3, 1999

No. 1
Informed decision making: an annotated bibliography and systematic review.

No. 2
Handling uncertainty when performing economic evaluation of healthcare interventions.
A review by Briggs AH, Gray AM.

No. 3
The role of expectancies in the placebo effect and their use in the delivery of health care: a systematic review.

No. 4

No. 5
Methods for evaluating area-wide and organisation-based interventions in health and health care: a systematic review.
By Ukomunne OC, Gilliford MC, Chinn S, Sterne JAC, Burney PGJ.

No. 6
Assessing the costs of healthcare technologies in clinical trials.
A review by Johnston K, Buxton MJ, Jones DR, Fitzpatrick R.

No. 7
Cooperatives and their primary care emergency centres: organisation and impact.
By Hallam L, Henthorne K.

No. 8
Screening for cystic fibrosis.
A review by Murray J, Cuckle H, Taylor G, Littlewood J, Hewison J.

No. 9
A review of the use of health status measures in economic evaluation.
By Brazier J, Deverill M, Green C, Harper R, Booth A.

No. 10
A review by Billingham LJ, Abrams KR, Jones DR.

No. 11
Antenatal and neonatal haemoglobinopathy screening in the UK: review and economic analysis.
By Zeuner D, Ades AE, Karnon J, Brown J, Dezauteux C, Anionwu EN.

No. 12
Assessing the quality of reports of randomised trials: implications for the conduct of meta-analyses.

No. 13
‘Early warning systems’ for identifying new healthcare technologies.
By Robert G, Stevens A, Gabbay J.

No. 14
A systematic review of the role of human papillomavirus testing within a cervical screening programme.

No. 15
Near patient testing in diabetes clinics: appraising the costs and outcomes.
By Grieve R, Beech R, Vincent J, Mazurkiewicz J.

No. 16
Positron emission tomography: establishing priorities for health technology assessment.
A review by Robert G, Milne R.

Vol. 4, 2000

No. 1
The estimation of marginal time preference in a UK-wide sample (TEMPUS) project.
A review by Cairns JA, van der Pol MM.

No. 2
Geriatric rehabilitation following fractures in older people: a systematic review.
No. 3  Screening for sickle cell disease and thalassaemia: a systematic review with supplementary research.
   By Davies SC, Cronin E, Gill M, Greengross P, Hickman M, Normand C.

No. 4  Community provision of hearing aids and related audiology services.
   A review by Reeves DJ, Alborz A, Hickson FS, Bamford JM.

No. 5  False-negative results in screening programmes: systematic review of impact and implications.
   By Petticrew MP, Sovden AJ, Lister-Sharp D, Wright K.

No. 6  Costs and benefits of community postnatal support workers: a randomised controlled trial.
   By Morrell CJ, Spihy H, Stewart P, Walters S, Morgan A.

No. 7  Implantable contraceptives (subdermal implants and hormonally impregnated intrauterine systems) versus other forms of reversible contraceptives: two systematic reviews to assess relative effectiveness, acceptability, tolerability and cost-effectiveness.

No. 8  An introduction to statistical methods for health technology assessment.
   A review by White SJ, Ashby D, Stevens A, Burls A, Hyde C.

No. 9  Disease-modifying drugs for multiple sclerosis: a rapid and systematic review.
   By Clegg A, Bryant J, Milne R.

No. 10  Publication and related biases.
   A review by Song F, Eastwood AJ, Gilbody S, Dudley L, Sutton AJ.

No. 11  Cost and outcome implications of the organisation of vascular services.
   By Michaels J, Brazier J, Palfreyman S, Shackley P, Slack R.

No. 12  Monitoring blood glucose control in diabetes mellitus: a systematic review.
   By Coster S, Guillford MC, Seed PT, Powrie JK, Swaminathan R.

No. 13  The effectiveness of domiciliary health visiting: a systematic review of international studies and a selective review of the British literature.

No. 14  The determinants of screening uptake and interventions for increasing uptake: a systematic review.

No. 15  The effectiveness and cost-effectiveness of prophylactic removal of wisdom teeth.
   A rapid review by Song F, O’Meara S, Wilson P, Goldie S, Kleijnen J.

No. 16  Ultrasound screening in pregnancy: a systematic review of the clinical effectiveness, cost-effectiveness and women’s views.

No. 17  A rapid and systematic review of the effectiveness and cost-effectiveness of the taxanes used in the treatment of advanced breast and ovarian cancer.
   By Lister-Sharp D, McDonagh MS, Khan KS, Kleijnen J.

No. 18  Liquid-based cytology in cervical screening: a rapid and systematic review.
   By Payne N, Chilcott J, McGooagan E.

No. 19  Randomised controlled trial of non-directive counselling, cognitive–behaviour therapy and usual general practitioner care in the management of depression as well as mixed anxiety and depression in primary care.

No. 20  Routine referral for radiography of patients presenting with low back pain: is patients’ outcome influenced by GPs’ referral for plain radiography?
   By Kerry S, Hilton S, Patel S, Dumbas D, Rink E, Lord J.

No. 21  Systematic reviews of wound care management. (3) antimicrobial agents for chronic wounds; (4) diabetic foot ulceration.
   By O’Meara S, Cullum N, Majid M, Sheldon T.

No. 22  Using routine data to complement and enhance the results of randomised controlled trials.
   By Lewsey JD, Leyland AH, Murray GD, Boddy FA.

No. 23  Coronary artery stents in the treatment of ischaemic heart disease: a rapid and systematic review.
   By Meads C, Cummins C, Jolly K, Stevens A, Burls A, Hyde C.

No. 24  Outcome measures for adult critical care: a systematic review.
   By Hayes JA, Black NA, Jenkinson C, Young JD, Rowan KM, Daly K, et al.

No. 25  A systematic review to evaluate the effectiveness of interventions to promote the initiation of breastfeeding.
   By Fairbank L, O’Meara S, Renfrew MJ, Woolridge M, Sovden AJ, Lister-Sharp D.

No. 26  Implantable cardioverter defibrillators: arrhythmias. A rapid and systematic review.
   By Parkes J, Bryant J, Milne R.

No. 27  Treatments for fatigue in multiple sclerosis: a rapid and systematic review.
   By Brañas P, Jordan R, Fry-Smith A, Burls A, Hyde C.

No. 28  Early asthma prophylaxis, natural history, skeletal development and economy (EASE): a pilot randomised controlled trial.

No. 29  Screening for hypercholesterolaemia versus case finding for familial hypercholesterolaemia: a systematic review and cost-effectiveness analysis.
   By Marks D, Wonderling D, Thorogood M, Lambert H, Humphries SE, Neil HAW.

No. 30  A rapid and systematic review of the clinical effectiveness and cost-effectiveness of glycoprotein IIb/IIIa antagonists in the medical management of unstable angina.
   By McDonagh MS, Bachmann LM, Golder S, Kleijnen J, ter Riet G.

No. 31  A randomised controlled trial of prehospital intravenous fluid replacement therapy in serious trauma.
   By Turner J, Nicholl J, Webber L, Cox H, Dixon S, Yates D.

No. 32  Intrathecal pumps for giving opioids in chronic pain: a systematic review.
   By Williams JE, Louw G, Towlerton G.

No. 33  Combination therapy (interferon alfa and ribavirin) in the treatment of chronic hepatitis C: a rapid and systematic review.
   By Shepherd J, Waugh N, Hewitson P.
Health Technology Assessment reports published to date

No. 34  A systematic review of comparisons of effect sizes derived from randomised and non-randomised studies.
   By MacLhose RR, Reeves BC, Harvey IM, Sheldon TA, Russell IT, Black AMS.

No. 35  Intravascular ultrasound-guided interventions in coronary artery disease: a systematic literature review, with decision-analytic modelling, of outcomes and cost-effectiveness.
   By Berry E, Kelly S, Hutton J, Lindsay HSJ, Blaxill JM, Evans JA, et al.

No. 36  A randomised controlled trial to evaluate the effectiveness and cost-effectiveness of counselling patients with chronic depression.
   By Simpson S, Corney R, Fitzgerald P, Beecham J.

No. 37  Systematic review of treatments for atopic eczema.
   By Hoare C, Li Wan Po A, Williams H.

No. 38  Bayesian methods in health technology assessment: a review.
   By Spiegelhalter DJ, Myles JP, Jones DR, Abrams KR.

No. 39  The management of dyspepsia: a systematic review.

No. 40  A systematic review of treatments for severe psoriasis.
   By Griffiths CEM, Clark CM, Chalmers RJG, Li Wan Po A, Williams HC.

Volume 5, 2001

No. 1  Clinical and cost-effectiveness of donepezil, rivastigmine and galantamine for Alzheimer’s disease: a rapid and systematic review.

No. 2  The clinical effectiveness and cost-effectiveness of riluzole for motor neurone disease: a rapid and systematic review.

No. 3  Economy and the economic evaluation of healthcare.
   By Sassi F, Archard L, Le Grand J.

No. 4  Quality-of-life measures in chronic diseases of childhood.
   By Eiser C, Morse R.

No. 5  Elicting public preferences for healthcare: a systematic review of techniques.

No. 6  General health status measures for people with cognitive impairment: learning disability and acquired brain injury.
   By Riensma RP, Forbes CA, Glanville JM, Eastwood AJ, Kleijnen J.

No. 7  An assessment of screening strategies for fragile X syndrome in the UK.
   By Pembrey ME, Barnicoat AJ, Carmichael B, Bobrow M, Turner G.

No. 8  Issues in methodological research: perspectives from researchers and commissioners.

No. 9  Systematic reviews of wound care management: (5) beds; (6) compression; (7) laser therapy, therapeutic ultrasound, electrotherapy and electromagnetic therapy.
   By Cullum N, Nelson EA, Flemming K, Sheldon T.

No. 10  Effects of educational and psychosocial interventions for adolescents with diabetes mellitus: a systematic review.
   By Hampson SE, Skinner TC, Hart J, Storey L, Gage H, Poizcroft D, et al.

No. 11  Effectiveness of autologous chondrocyte transplantation for hyaline cartilage defects in knees: a rapid and systematic review.
   By Johanputra P, Parry D, Fry-Smith A, Burls A.

No. 12  Statistical assessment of the learning curves of health technologies.
   By Ramsay CR, Grant AM, Wallace SA, Garthwaite PH, Monk AF, Russell IT.

No. 13  The effectiveness and cost-effectiveness of temozolomide for the treatment of recurrent malignant glioma: a rapid and systematic review.
   By Dinnes J, Cave C, Huang S, Major K, Milne R.

No. 14  A rapid and systematic review of the clinical effectiveness and cost-effectiveness of debriding agents in treating surgical wounds healing by secondary intention.
   By Lewis R, Whiting P, ter Riet G, O’Meara S, Glanville J.

No. 15  Home treatment for mental health problems: a systematic review.

No. 16  How to develop cost-conscious guidelines.
   By Eccles M, Mason J.

No. 17  The role of specialist nurses in multiple sclerosis: a rapid and systematic review.
   By De Broe S, Christopher F, Waugh N.

No. 18  A rapid and systematic review of the clinical effectiveness and cost-effectiveness of orlistat in the management of obesity.
   By O’Meara S, Riemsma R, Shirran L, Mathet L, ter Riet G.

No. 19  The clinical effectiveness and cost-effectiveness of pioglitazone for type 2 diabetes mellitus: a rapid and systematic review.
   By Chilcott J, Wight J, Lloyd Jones M, Tappenden P.

No. 20  Extended scope of nursing practice: a multicentre randomised controlled trial of appropriately trained nurses and preregistration house officers in pre-operative assessment in elective general surgery.

No. 21  Systematic reviews of the effectiveness of day care for people with severe mental disorders: (1) Acute day hospital versus admission; (2) Vocational rehabilitation; (3) Day hospital versus outpatient care.

No. 22  The measurement and monitoring of surgical adverse events.
   By Bruce J, Russell EM, Mollison J, Krukowski ZH.

No. 23  Action research: a systematic review and guidance for assessment.
   By Waterman H, Tillen D, Dickson R, de Koning K.

No. 24  A rapid and systematic review of the clinical effectiveness and cost-effectiveness of gemcitabine for the treatment of pancreatic cancer.
No. 25
A rapid and systematic review of the evidence for the clinical effectiveness and cost-effectiveness of irinotecan, oxaliplatin and raltitrexed for the treatment of advanced colorectal cancer.
By Lloyd Jones M, Hummel S, Bansback N, Orr B, Seymour M.

No. 26
Comparison of the effectiveness of inhaler devices in asthma and chronic obstructive airways disease: a systematic review of the literature.

No. 27
The cost-effectiveness of magnetic resonance imaging for investigation of the knee joint.

No. 28
A rapid and systematic review of the clinical effectiveness and cost-effectiveness of topotecan for ovarian cancer.
By Forbes C, Shirran L, Bagnall A-M, Duffy S, ter Riet G.

No. 29
Superseded by a report published in a later volume.

No. 30
The role of radiography in primary care patients with low back pain of at least 6 weeks duration: a randomised (unblinded) controlled trial.
By Kendrick D, Fielding K, Bentley E, Miller P, Kerslake R, Pringle M.

No. 31
Design and use of questionnaires: a review of best practice applicable to surveys of health service staff and patients.

No. 32
A rapid and systematic review of the clinical effectiveness and cost-effectiveness of paclitaxel, docetaxel, gemcitabine and vinorelbine in non-small-cell lung cancer.
By Clegg A, Scott DA, Sidhu M, Hewitson P, Waugh N.

No. 33
Subgroup analyses in randomised controlled trials: quantifying the risks of false-positives and false-negatives.
By Brooks ST, Whitley E, Peters TJ, Mulheran PA, Egger M, Davey Smith G.

No. 34
Depot antipsychotic medication in the treatment of patients with schizophrenia: (1) Meta-review; (2) Patient and nurse attitudes.
By David AS, Adams C.

No. 35
A systematic review of controlled trials of the effectiveness and cost-effectiveness of brief psychological treatments for depression.

No. 36
Cost analysis of child health surveillance.
By Sanderson D, Wright D, Acton C, Durce D.

Volume 6, 2002
No. 1
A study of the methods used to select review criteria for clinical audit.
By Hearnsaw H, Harker R, Cheater F, Baker R, Grimshaw G.

No. 2
Fludarabine as second-line therapy for B cell chronic lymphocytic leukaemia: a technology assessment.

No. 3
Rituximab as third-line treatment for refractory or recurrent Stage III or IV follicular non-Hodgkin’s lymphoma: a systematic review and economic evaluation.

No. 4
A systematic review of discharge arrangements for older people.

No. 5
The clinical effectiveness and cost-effectiveness of inhaler devices used in the routine management of chronic asthma in older children: a systematic review and economic evaluation.
By Peters J, Stevenson M, Beverley C, Lim J, Smith S.

No. 6
The clinical effectiveness and cost-effectiveness of sulfatrame in the management of obesity: a technology assessment.
By O’Meara S, Riemsma R, Shirran L, Mather L, ter Riet G.

No. 7
The cost-effectiveness of magnetic resonance angiography for carotid artery stenosis and peripheral vascular disease: a systematic review.

No. 8
Promoting physical activity in South Asian Muslim women through ‘exercise on prescription’.
By Carroll B, Ali N, Azam N.

No. 9
Zanamivir for the treatment of influenza in adults: a systematic review and economic evaluation.

No. 10
A review of the natural history and epidemiology of multiple sclerosis: implications for resource allocation and health economic models.
By Richards RG, Sampson FC, Beard SM, Tappenden P.

No. 11
Screening for gestational diabetes: a systematic review and economic evaluation.
By Scott DA, Loveman E, McIntyre L, Waugh N.

No. 12
The clinical effectiveness and cost-effectiveness of surgery for people with morbid obesity: a systematic review and economic evaluation.

No. 13
The clinical effectiveness of trastuzumab for breast cancer: a systematic review.

No. 14
The clinical effectiveness and cost-effectiveness of vinorelbine for breast cancer: a systematic review and economic evaluation.

No. 15
A systematic review of the effectiveness and cost-effectiveness of metal-on-metal hip resurfacing arthroplasty for treatment of hip disease.
By Vale L, Wyness L, McCormack K, McKenzie L, Brazzelli M, Stearns SC.

No. 16
The clinical effectiveness and cost-effectiveness of bupropion and nicotine replacement therapy for smoking cessation: a systematic review and economic evaluation.
By Woolacott NE, Jones L, Forbes CA, Mather LC, Sowden AJ, Song FJ, et al.

No. 17
A systematic review of effectiveness and economic evaluation of new drug treatments for juvenile idiopathic arthritis: etanercept.
By Cammins C, Connock M, Fry-Smith A, Burts A.

No. 18
No. 19
By Bryant J, Loveman E, Chase D, Mihaylova B, Cave C, Gerard K, et al.

No. 20
Clinical medication review by a pharmacist of patients on repeat prescriptions in general practice: a randomised controlled trial.
By Zermansky AG, Petty DR, Raynor DK, Lowe CJ, Freemantle N, Vail A.

No. 21
The effectiveness of infliximab and etanercept for the treatment of rheumatoid arthritis: a systematic review and economic evaluation.
By Jobanputra P, Barton P, Bryan S, Burls A.

No. 22
A systematic review and economic evaluation of computerised cognitive behaviour therapy for depression and anxiety.
By Kaltenhauler E, Shackley P, Stevens K, Beverley C, Parry G, Chilcott J.

No. 23
A systematic review and economic evaluation of pegylated liposomal doxorubicin hydrochloride for ovarian cancer.
By Forbes C, Wilby J, Richardson G, Sculpher M, Mathers L, Reimsmra R.

No. 24
A systematic review of the effectiveness of interventions based on a stage-of-change approach to promote individual behaviour change.

No. 25
A systematic review update of the clinical effectiveness and cost-effectiveness of glycoprotein IIb/IIIa antagonists.

No. 26
A systematic review of the effectiveness, cost-effectiveness and barriers to implementation of thrombolytic and neuroprotective therapy for acute ischaemic stroke in the NHS.

No. 27
A randomised controlled crossover trial of nurse practitioner versus doctor-led outpatient care in a bronchiectasis clinic.

No. 28
By Adi Y, Ashcroft D, Browne K, Beech A, Fry-Smith A, Hyde C.

No. 29
Treatment of established osteoporosis: a systematic review and cost–utility analysis.
By Kanis JA, Brazier JE, Stevenson M, Calvert NW, Lloyd Jones M.

No. 30
Which anaesthetic agents are cost-effective in day surgery? Literature review, national survey of practice and randomised controlled trial.

No. 31
Screening for hepatitis C among injecting drug users and in genitourinary medicine clinics: systematic reviews of effectiveness, modelling study and national survey of current practice.

No. 32
The measurement of satisfaction with healthcare: implications for practice from a systematic review of the literature.

No. 33
The effectiveness and cost-effectiveness of imatinib in chronic myeloid leukaemia: a systematic review.
By Garside R, Round A, Dalziel K, Stein K, Royle R.

No. 34
A comparative study of hypertonic saline, daily and alternate-day rhDNase in children with cystic fibrosis.

No. 35
A systematic review of the costs and effectiveness of different models of paediatric home care.

**Volume 7, 2003**

No. 1
How important are comprehensive literature searches and the assessment of trial quality in systematic reviews? Empirical study.
By Egger M, Juni P, Bartlett C, Holenstein F, Sterne J.

No. 2
Systematic review of the effectiveness and cost-effectiveness, and economic evaluation, of home versus hospital or satellite unit haemodialysis for people with end-stage renal failure.

No. 3
Systematic review and economic evaluation of the effectiveness of infliximab for the treatment of Crohn’s disease.
By Clark W, Raftery J, Barton P, Song F, Fry-Smith A, Burls A.

No. 4
A review of the clinical effectiveness and cost-effectiveness of routine anti-D prophylaxis for pregnant women who are rhesus negative.

No. 5
Systematic review and evaluation of the use of tumour markers in paediatric oncology: Ewing’s sarcoma and neuroblastoma.

No. 6
The cost-effectiveness of screening for Helicobacter pylori to reduce mortality and morbidity from gastric cancer and peptic ulcer disease: a discrete-event simulation model.

No. 7
The clinical effectiveness and cost-effectiveness of routine dental checks: a systematic review and economic evaluation.

No. 8
A multicentre randomised controlled trial assessing the costs and benefits of using structured information and analysis of women’s preferences in the management of menorrhagia.

No. 9
Clinical effectiveness and cost–utility of photodynamic therapy for wet age-related macular degeneration: a systematic review and economic evaluation.
By Meads C, Salas C, Roberts T, Moore D, Fry-Smith A, Hyde C.

No. 10
Evaluation of molecular tests for prenatal diagnosis of chromosome abnormalities.
No. 11
First and second trimester antenatal screening for Down's syndrome: the results of the Serum, Urine and Ultrasound Screening Study (SURUSS).
By Wald NJ, Rodeck C, Hackshaw AK, Walters J, Chitty L, Mackinson AM.

No. 12
The effectiveness and cost-effectiveness of ultrasound locating devices for central venous access: a systematic review and economic evaluation.
By Calvert N, Hind D, McWilliams RG, Thomas SM, Beverley C, Davidson A.

No. 13
A systematic review of atypical antipsychotics in schizophrenia.

No. 14
Prostate Testing for Cancer and Treatment (ProtecT) feasibility study.
By Donovan J, Hamdy F, Neal D, Peters T, Oliver S, Brindle L, et al.

No. 15
Early thrombolysis for the treatment of acute myocardial infarction: a systematic review and economic evaluation.

No. 16
Screening for fragile X syndrome: a literature review and modelling.
By Song FJ, Barton P, Sleightholme V, Yao GL, Fry-Smith A.

No. 17
Systematic review of endoscopic sinus surgery for nasal polyps.
By Dalziel K, Stein K, Round A, Garside R, Royle P.

No. 18
Towards efficient guidelines: how to monitor guideline use in primary care.
By Hutchinson A, McIntosh A, Cox S, Gilbert C.

No. 19
Effectiveness and cost-effectiveness of acute hospital-based spinal cord injuries services: systematic review.
By Bagnall A-M, Jones L, Richardson G, Duffy S, Riemsma R.

No. 20
Prioritisation of health technology assessment. The PATHS model: methods and case studies.
By Townsend J, Buxton M, Harper G.

No. 21

No. 22
By Loveman E, Cave C, Green C, Royle P, Dunn N, Waugh N.

No. 23
The role of modelling in prioritising and planning clinical trials.
By Chilcott J, Brennan A, Booth A, Karnon J, Tappenden P.

No. 24
Cost–benefit evaluation of routine influenza immunisation in people 65–74 years of age.
By Allsup S, Gosney M, Haycox A, Regan M.

No. 25
The clinical and cost-effectiveness of pulsatile machine perfusion versus cold storage of kidneys for transplantation retrieved from heart-beating and non-heart-beating donors.
By Wight J, Chilcott J, Holmes M, Brewer N.

No. 26
Can randomised trials rely on existing electronic data? A feasibility study to explore the value of routine data in health technology assessment.
By Williams JG, Cheung WY, Cohen DR, Hutchings HA, Longo MF, Russell IT.

No. 27
Evaluating non-randomised intervention studies.

No. 28
A randomised controlled trial to assess the impact of a package comprising a patient-oriented, evidence-based self-help guidebook and patient-centred consultations on disease management and satisfaction in inflammatory bowel disease.

No. 29
The effectiveness of diagnostic tests for the assessment of shoulder pain due to soft tissue disorders: a systematic review.
By Dinnes J, Loveman E, McIntyre L, Waugh N.

No. 30
The value of digital imaging in diabetic retinopathy.

No. 31
Lowering blood pressure to prevent myocardial infarction and stroke: a new preventive strategy.
By Law M, Wald N, Morris J.

No. 32
Clinical and cost-effectiveness of capetibatine and tegafur with uracil for the treatment of metastatic colorectal cancer: systematic review and economic evaluation.
By Ward S, Kaltenhalter E, Cowan J, Brewer N.

No. 33
By Hummel S, Paisley S, Morgan A, Currie E, Brewer N.

No. 34
Literature searching for clinical and cost-effectiveness studies used in health technology assessment reports carried out for the National Institute for Clinical Excellence appraisal system.
By Royle P, Waugh N.

No. 35
Systematic review and economic decision modelling for the prevention and treatment of influenza A and B.

No. 36
A randomised controlled trial to evaluate the clinical and cost-effectiveness of Hickman line insertions in adult cancer patients by nurses.
By Boland A, Haycox A, Bagust A, Fitzsimmons L.

No. 37
Redesigning postnatal care: a randomised controlled trial of protocol-based midwifery-led care focused on individual women's physical and psychological health needs.

No. 38
Estimating implied rates of discount in healthcare decision-making.
By West RR, McNabb R, Thompson AGH, Sheldon TA, Grimley Evans J.
No. 39  Systematic review of isolation policies in the hospital management of methicillin-resistant *Staphylococcus aureus*; a review of the literature with epidemiological and economic modelling.  
By Cooper BS, Stone SP, Gibbler CC, Cookson BD, Roberts JA, Medley GF, et al.

No. 40  Treatments for spasticity and pain in multiple sclerosis: a systematic review.  
By Beard S, Hunn A, Wight J.

No. 41  The inclusion of reports of randomised trials published in languages other than English in systematic reviews.  
By Moher D, Pham B, Lawson ML, Klassen TP.

No. 42  The impact of screening on future health-promoting behaviours and health beliefs: a systematic review.  

*Volume 8, 2004*

No. 1  What is the best imaging strategy for acute stroke?  
By Wardlaw JM, Keir SL, Seymour J, Lewis S, Sandercock PAG, Dennis MS, et al.

No. 2  Systematic review and modelling of the investigation of acute and chronic chest pain presenting in primary care.  
By Mant J, McManus RJ, Oakes RAL, Delaney BC, Barton PM, Deeks JJ, et al.

No. 3  The effectiveness and cost-effectiveness of microwave and thermal balloon endometrial ablation for heavy menstrual bleeding: a systematic review and economic modelling.  

No. 4  A systematic review of the role of bisphosphonates in metastatic disease.  

No. 5  Systematic review of the clinical effectiveness and cost-effectiveness of capecitabine (*Xeloda*) for locally advanced and/or metastatic breast cancer.  
By Jones L, Hawkins N, Westwood M, Wright K, Richardson G, Riemsma R.

No. 6  Effectiveness and efficiency of guideline dissemination and implementation strategies.  

No. 7  Clinical effectiveness and costs of the Sugarbaker procedure for the treatment of pseudomyxoma peritonei.  
By Bryant J, Clegg AJ, Sidhu MK, Brodin H, Royle P, Davidson P.

No. 8  Psychological treatment for insomnia in the regulation of long-term hypnotic drug use.  
By Morgan K, Dixon S, Mathers N, Thompson J, Tomeny M.

No. 9  Improving the evaluation of therapeutic interventions in multiple sclerosis: development of a patient-based measure of outcome.  
By Hobart JC, Riazi A, Lamping DL, Fitzpatrick R, Thompson AJ.

No. 10  A systematic review and economic evaluation of magnetic resonance cholangiopancreatography compared with diagnostic endoscopic retrograde cholangiopancreatography.  

No. 11  The use of modelling to evaluate new drugs for patients with a chronic condition: the case of antibodies against tumour necrosis factor in rheumatoid arthritis.  

By Pandor A, Eastham J, Beverley C, Chilcott J, Paisley S.

By Czoski-Murray C, Warren E, Chilcott J, Beverley C, Pyllaki MA, Cowan J.

No. 14  Routine examination of the newborn: the EMREN study. Evaluation of an extension of the midwife role including a randomised controlled trial of appropriately trained midwives and paediatric senior house officers.  

No. 15  Involving consumers in research and development agenda setting for the NHS: developing an evidence-based approach.  

No. 16  A multi-centre randomised controlled trial of minimally invasive direct coronary bypass grafting versus percutaneous transluminal coronary angioplasty with stenting for proximal stenosis of the left anterior descending coronary artery.  

No. 17  Does early magnetic resonance imaging influence management or improve outcome in patients referred to secondary care with low back pain? A pragmatic randomised controlled trial.  
By Gilbert FJ, Grant AM, Gillan MGC, Vale L, Scott NW, Campbell MK, et al.

No. 18  The clinical and cost-effectiveness of anakinra for the treatment of rheumatoid arthritis in adults: a systematic review and economic analysis.  
By Clark W, Jhanuputra P, Barton P, Burls A.

No. 19  A rapid and systematic review and economic evaluation of the clinical and cost-effectiveness of newer drugs for treatment of mania associated with bipolar affective disorder.  

No. 20  Liquid-based cytology in cervical screening: an updated rapid and systematic review and economic analysis.  

No. 21  Systematic review of the long-term effects and economic consequences of treatments for obesity and implications for health improvement.  

No. 22  Autoantibody testing in children with newly diagnosed type 1 diabetes mellitus.  
By Dretzke J, Cummins C, Sandercock J, Fry-Smith A, Barrett T, Burls A.
No. 23
Clinical effectiveness and cost-effectiveness of prehospital intravenous fluids in trauma patients.
By Dretzke J, Sandercock J, Bayliss S, Burls A.

No. 24
Newer hypnotic drugs for the short-term management of insomnia: a systematic review and economic evaluation.

No. 25
Development and validation of methods for assessing the quality of diagnostic accuracy studies.
By Whiting P, Rutjes AWS, Dinnnes J, Reitsma JB, Bossuyt PMM, Kleijnen J.

No. 26
EVALUATE hysterectomy trial: a multicentre randomised trial comparing abdominal, vaginal and laparoscopic methods of hysterectomy.

No. 27
By Tappenden P, Chilcott JB, Eggington S, Oakley J, McCabe C.

No. 28
By Dalziel K, Rond A, Stein K, Garside R, Price A.

No. 29
VenUS I: a randomised controlled trial of two types of bandage for treating venous leg ulcers.
By Igleias C, Nelson EA, Cullum NA, Torgerson DJ on behalf of the VenUS Team.

No. 30
Systematic review of the effectiveness and cost-effectiveness, and economic evaluation, of myocardial perfusion scintigraphy for the diagnosis and management of angina and myocardial infarction.

No. 31
A pilot study on the use of decision theory and value of information analysis as part of the NHS Health Technology Assessment programme.
By Claxton K, Ginnelly L, Scruphler M, Philips Z, Palmer S.

No. 32
The Social Support and Family Health Study: a randomised controlled trial and economic evaluation of two alternative forms of postnatal support for mothers living in disadvantaged inner-city areas.

No. 33
Psychosocial aspects of genetic screening of pregnant women and newborns: a systematic review.
By Green JM, Hewison J, Bekker HL, Bryant, Cackle HS.

No. 34
Evaluation of abnormal uterine bleeding: comparison of three outpatient procedures within cohorts defined by age and menopausal status.

No. 35
Coronary artery stents: a rapid systematic review and economic evaluation.

No. 36
Review of guidelines for good practice in decision-analytic modelling in health technology assessment.

No. 37
Rituximab (MabThera®) for aggressive non-Hodgkin’s lymphoma: systematic review and economic evaluation.
By Knight C, Hind D, Brewer N, Abbott V.

No. 38
Clinical effectiveness and cost-effectiveness of clopidogrel and modified-release dipyridamole in the secondary prevention of occlusive vascular events: a systematic review and economic evaluation.
By Jones L, Grifflin S, Palmer S, Main C, Orton V, Scruphler M, et al.

No. 39
By Shepherd J, Brodin H, Cave C, Waugh N, Price A, Gabbay J.

No. 40
Clopidogrel used in combination with aspirin compared with aspirin alone in the treatment of non-ST-segment-elevation acute coronary syndromes: a systematic review and economic evaluation.
By Main C, Palmer S, Grifflin S, Jones L, Orton V, Scruphler M, et al.

No. 41
Provision, uptake and cost of cardiac rehabilitation programmes: improving services to under-represented groups.
By Beswick AD, Rees K, Griebisch I, Taylor FC, Burke M, West RR, et al.

No. 42
Involving South Asian patients in clinical trials.
By Hussain-Gambles M, Leese B, Atkin K, Brown J, Mason S, Tovey P.

No. 43
Clinical and cost-effectiveness of continuous subcutaneous insulin infusion for diabetes.
By Colquitt JL, Green C, Sidhu MK, Hartwell D, Waugh N.

No. 44
Identification and assessment of ongoing trials in health technology assessment reviews.

No. 45
Systematic review and economic evaluation of a long-acting insulin analogue, insulin glargine.
By Warren E, Weatherley-Jones E, Chilcott J, Beverley C.

No. 46
Supplementation of a home-based exercise programme with a class-based programme for people with osteoarthritis of the knees: a randomised controlled trial and health economic analysis.

No. 47
Clinical and cost-effectiveness of once-daily versus more frequent use of same potency topical corticosteroids for atopic eczema: a systematic review and economic evaluation.
By Green C, Colquitt JL, Kirby J, Davidson P, Payne E.

No. 48
Acupuncture of chronic headache disorders in primary care: randomised controlled trial and economic analysis.

No. 49
Generalisability in economic evaluation of NHS clinical trials.

No. 50
Virtual outreach: a randomised controlled trial and economic evaluation of joint teleconferenced medical consultations.
No. 1
Randomised controlled multiple-treatment comparison to provide a cost-effectiveness rationale for the selection of antimicrobial therapy in acne.

No. 2
Do the findings of case series studies vary significantly according to methodological characteristics?
By Dalziel K, Bond A, Stein K, Garside R, Castelnuovo E, Payne L.

No. 3
Improving the referral process for familial breast cancer genetic counselling: findings of three randomised controlled trials.

No. 4
Randomised evaluation of alternative electrosurgical modalities to treat bladder outflow obstruction in men with benign prostatic hyperplasia.
By Fowler C, McAllister W, Phill R, Karim O, Yang Q.

No. 5
A pragmatic randomised controlled trial of the cost-effectiveness of palliative therapies for patients with inoperable oesophageal cancer.
By Shenhine J, McNamee P, Steen N, Bond J, Griffin SM.

No. 6
Impact of computer-aided detection prompts on the sensitivity and specificity of screening mammography.
By Taylor P, Champness J, Given-Wilson R, Johnston K, Potts H.

No. 7
Issues in data monitoring and interim analysis of trials.
By Grant AM, Altman DG, Babiker AB, Campbell MK, Clemens FJ, Darbyshire JH, et al.

No. 8
Lay public’s understanding of equipoise and randomisation in randomised controlled trials.

No. 9
Clinical and cost-effectiveness of electroconvulsive therapy for depressive illness, schizophrenia, catatonia and mania: systematic reviews and economic modelling studies.
By Greenhalgh J, Knight C, Hind D, Beverley C, Walters S.

No. 10
Measurement of health-related quality of life for people with dementia: development of a new instrument (DEMQOL) and an evaluation of current methodology.

No. 11
Clinical effectiveness and cost-effectiveness of drotrecogin alfa (activated) (Xigris®) for the treatment of severe sepsis in adults: a systematic review and economic evaluation.

No. 12
A methodological review of how heterogeneity has been examined in systematic reviews of diagnostic test accuracy.
By Dinnes J, Deeks J, Kirby J, Roderick P.

No. 13
Cervical screening programmes: can automation help? Evidence from systematic reviews, an economic analysis and a simulation modelling exercise applied to the UK.
By Willis BH, Barton P, Pearmain P, Bryan S, Hyde C.

No. 14
Laparoscopic surgery for inguinal hernia repair: systematic review of effectiveness and economic evaluation.

No. 15
Clinical effectiveness, tolerability and cost-effectiveness of newer drugs for epilepsy in adults: a systematic review and economic evaluation.

No. 16
A randomised controlled trial to compare the cost-effectiveness of tricyclic antidepressants, selective serotonin reuptake inhibitors and lofepramine.

No. 17
Clinical effectiveness and cost-effectiveness of immediate angioplasty for acute myocardial infarction: systematic review and economic evaluation.

No. 18
A randomised controlled comparison of alternative strategies in stroke care.
By Kalra L, Evans A, Perez I, Knapp M, Swift C, Donaldson N.

No. 19
The investigation and analysis of critical incidents and adverse events in healthcare.
By Wooshynowsychn M, Rogers S, Taylor-Adams S, Vincent C.

No. 20
Potential use of routine databases in health technology assessment.
By Raftery J, Roderick P, Stevens A.

No. 21

No. 22
A systematic review and economic evaluation of alendronate, etidronate, risedronate, teriparatide and corticosteroids for the prevention and treatment of postmenopausal osteoporosis.
By Stevenson M, Lloyd Jones M, De Nigris E, Brewer N, Davis S, Oakley J.

No. 23
A systematic review to examine the impact of psycho-educational interventions on health outcomes and costs in adults and children with difficult asthma.

No. 24
An evaluation of the costs, effectiveness and quality of renal replacement therapy provision in renal satellite units in England and Wales.

No. 25
Imatinib for the treatment of patients with unresectable and/or metastatic gastrointestinal stromal tumours: systematic review and economic evaluation.

No. 26
Indirect comparisons of competing interventions.

No. 27
Cost-effectiveness of alternative strategies for the initial medical management of non-ST elevation acute coronary syndrome: systematic review and decision-analytical modelling.
No. 28
Outcomes of electrically stimulated gracilis neosphincter surgery.
By Tillin T, Chambers M, Feldman R.

No. 29
The effectiveness and cost-effectiveness of pimecrolimus and tacrolimus for atopic eczema: a systematic review and economic evaluation.

No. 30
Systematic review on urine albumin testing for early detection of diabetic complications.

No. 31
Randomised controlled trial of the cost-effectiveness of water-based therapy for lower limb osteoarthritis.
By Cochrane T, Davey RG, Matthes Edwards SM.

No. 32
Longer term clinical and economic benefits of offering acupuncture care to patients with chronic low back pain.

No. 33
Cost-effectiveness and safety of epidural steroids in the management of sciatica.
By Price C, Arden N, Coglan L, Rogers P.

No. 34
The British Rheumatoid Outcome Study Group (BROSG) randomised controlled trial to compare the effectiveness and cost-effectiveness of aggressive versus symptomatic therapy in established rheumatoid arthritis.
By Symmons D, Tricker K, Roberts C, Davies L, Dawes P, Scott DL.

No. 35
Conceptual framework and systematic review of the effects of participants' and professionals' preferences in randomised controlled trials.

No. 36
The clinical and cost-effectiveness of implantable cardioverter defibrillators: a systematic review.
By Bryant J, Brodin H, Loveman E, Payne E, Clegg A.

No. 37
A trial of problem-solving by community mental health nurses for anxiety, depression and life difficulties among general practice patients. The CPN-GP study.

No. 38
The causes and effects of socio-demographic exclusions from clinical trials.

No. 39
Is hydrotherapy cost-effective? A randomised controlled trial of combined hydrotherapy programmes compared with physiotherapy land techniques in children with juvenile idiopathic arthritis.

No. 40
A randomised controlled trial and cost-effectiveness study of systematic screening (targeted and total population screening) versus routine practice for the detection of atrial fibrillation in people aged 65 and over. The SAFE study.

No. 41
Displaced intracapsular hip fractures in fit, older people: a randomised comparison of reduction and fixation, bipolar hemiarthroplasty and total hip arthroplasty.
By Keating J, Grant A, Masson M, Scott NW, Forbes JF.

No. 42
Long-term outcome of cognitive behaviour therapy clinical trials in central Scotland.

No. 43
The effectiveness and cost-effectiveness of dual-chamber pacemakers compared with single-chamber pacemakers for bradycardia due to atrioventricular block or sick sinus syndrome: systematic review and economic evaluation.
By Castelnuovo E, Stein K, Pitt M, Garside R, Payne E.

No. 44
Newborn screening for congenital heart defects: a systematic review and cost-effectiveness analysis.

No. 45
The clinical and cost-effectiveness of left ventricular assist devices for end-stage heart failure: a systematic review and economic evaluation.

No. 46
The effectiveness of the Heidelberg Retina Tomograph and laser diagnostic glaucoma scanning system (GDx) in detecting and monitoring glaucoma.
By Kwartz AJ, Henson DB, Harper RA, Spencer AF, McLeod D.

No. 47
Clinical and cost-effectiveness of autologous chondrocyte implantation for cartilage defects in knee joints: systematic review and economic evaluation.

No. 48
Systematic review of effectiveness of different treatments for childhood retinoblastoma.

No. 49
Towards evidence-based guidelines for the prevention of venous thromboembolism: systematic reviews of mechanical methods, oral anticoagulation, dextran and regional anaesthesia as thromboprophylaxis.

No. 50
The effectiveness and cost-effectiveness of parent training/education programmes for the treatment of conduct disorder, including oppositional defiant disorder, in children.

Volume 10, 2006

No. 1
The clinical and cost-effectiveness of donepezil, rivastigmine, galantamine and memantine for Alzheimer’s disease.

No. 2
FOOD: a multicentre randomised trial evaluating feeding policies in patients admitted to hospital with a recent stroke.
By Dennis M, Lewis S, Granswick G, Forbes J.

No. 3
The clinical effectiveness and cost-effectiveness of computed tomography screening for lung cancer: systematic reviews.
No. 4  
A systematic review of the effectiveness and cost-effectiveness of neuromaging assessments used to visualise the seizure focus in people with refractory epilepsy being considered for surgery.  

No. 5  
Comparison of conference abstracts and presentations with full-text articles in the health technology assessments of rapidly evolving technologies.  
By Dundar Y, Dodd S, Dickson R, Walley T, Haycox A, Williamson PR.

No. 6  
Systematic review and evaluation of methods of assessing urinary incontinence.  

No. 7  

No. 8  
Surveillance of Barrett’s oesophagus: exploring the uncertainty through systematic review, expert workshop and economic modelling.  
By Garside R, Pitt M, Somerville M, Stein K, Price A, Gilbert N.

No. 9  
Topotecan, pegylated liposomal doxorubicin hydrochloride and paclitaxel for second-line or subsequent treatment of advanced ovarian cancer: a systematic review and economic evaluation.  

No. 10  
Evaluation of molecular techniques in prediction and diagnosis of cytomegalovirus disease in immunocompromised patients.  
By Szczepura A, Westmoreland D, Vinogradova Y, Fox J, Clark M.

No. 11  
Screening for thrombophilia in high-risk situations: systematic review and cost-effectiveness analysis. The Thrombosis Risk and Economic Assessment of Thrombophilia Screening (TREATS) study.  

No. 12  
A series of systematic reviews to inform a decision analysis on sampling and treating infected diabetic foot ulcers.  

No. 13  
Randomised clinical trial, observational study and assessment of cost-effectiveness of the treatment of varicose veins (REACTIV trial).  

No. 14  
The cost-effectiveness of screening for oral cancer in primary care.  
By Speight PM, Palmer S, Moles DR, Downer MC, Smith DH, Henriksson M, et al.

No. 15  

No. 16  

No. 17  
Randomised controlled trials of conventional antipsychotic versus new atypical drugs, and new atypical drugs versus clozapine, in people with schizophrenia responding poorly to, or intolerant of, current drug treatment.  
By Lewis SW, Davies L, Jones PB, Barnes TRE, Murray RM, Kerwin R, et al.

No. 18  
Diagnostic tests and algorithms used in the investigation of haematuria: systematic reviews and economic evaluation.  

No. 19  
Cognitive behavioural therapy in addition to antipsychotic therapy for irritable bowel syndrome in primary care: randomised controlled trial.  

No. 20  
A systematic review of the clinical effectiveness and cost-effectiveness of enzyme replacement therapies for Fabry’s disease and mucopolysaccharidosis type 1.  

No. 21  
Health benefits of antiviral therapy for mild chronic hepatitis C: randomised controlled trial and economic evaluation.  
By Wright M, Grieve R, Roberts J, Main J, Thomas HC on behalf of the UK Mild Hepatitis C Trial Investigators.

No. 22  
Pressure relieving support surfaces: a randomised evaluation.  

No. 23  
A systematic review and economic model of the effectiveness and cost-effectiveness of methylphenidate, dexamphetamine and atomoxetine for the treatment of attention deficit hyperactivity disorder in children and adolescents.  

No. 24  
The clinical effectiveness and cost-effectiveness of enzyme replacement therapy for Gaucher’s disease: a systematic review.  

No. 25  
Effectiveness and cost-effectiveness of salicylic acid and cryotherapy for cutaneous warts. An economic decision model.  

No. 26  
A systematic literature review of the effectiveness of non-pharmacological interventions to prevent wandering in people with dementia and evaluation of the ethical implications and acceptability of their use.  

No. 27  
A review of the evidence on the effects and costs of implantable cardioverter defibrillator therapy in different patient groups, and modelling of cost-effectiveness and cost-utility for these studies in a UK context.  
No. 28  Adefovir dipivoxil and pegylated interferon alfa-2a for the treatment of chronic hepatitis B: a systematic review and economic evaluation.
By Shepherd J, Jones J, Takeda A, Davidson P, Price A.

No. 29  An evaluation of the clinical and cost-effectiveness of pulmonary artery catheters in patient management in intensive care: a systematic review and a randomised controlled trial.
By Harvey S, Stevens K, Harrison D, Young D, Brampton W, McCabe C, et al.

No. 30  Accurate, practical and cost-effective assessment of carotid stenosis in the UK.
By Wardlaw JM, Chappell FM, Stevenson M, De Nigris E, Thomas S, Gillard J, et al.

No. 31  Etanercept and infliximab for the treatment of psoriatic arthritis: a systematic review and economic evaluation.

No. 32  The cost-effectiveness of testing for hepatitis C in former injecting drug users.

No. 33  Computerised cognitive behaviour therapy for depression and anxiety update: a systematic review and economic evaluation.

No. 34  Cost-effectiveness of using prognostic information to select women with breast cancer for adjuvant systemic therapy.

No. 35  Psychological therapies including dialectical behaviour therapy for borderline personality disorder: a systematic review and preliminary economic evaluation.

No. 36  Clinical effectiveness and cost-effectiveness of tests for the diagnosis and investigation of urinary tract infection in children: a systematic review and economic model.

No. 37  Cognitive behavioural therapy in chronic fatigue syndrome: a randomised controlled trial of an outpatient group programme.
By O’Dowd H, Gladwell P, Rogers CA, Hollinghurst S, Gregory A.

No. 39  The effectiveness and cost-effectiveness of computed tomography screening for coronary artery disease: systematic review.
By Waugh N, Black C, Walker S, McIntyre L, Cummins E, HILLIS G.

No. 40  What are the clinical outcome and cost-effectiveness of endoscopy undertaken by nurses when compared with doctors? A Multi-Institution Nurse Endoscopy Trial (MINuET).

No. 41  The clinical and cost-effectiveness of oxaliplatin and capecitabine for the adjuvant treatment of colon cancer: systematic review and economic evaluation.
By Pandor A, Eggington S, Paisley S, Tappenden P, Sutcliffe P.

No. 42  A systematic review of the effectiveness of adalimumab, etanercept and infliximab for the treatment of rheumatoid arthritis in adults and an economic evaluation of their cost-effectiveness.

No. 43  Telemedicine in dermatology: a randomised controlled trial.
By Bows IR, Collins K, Walters SJ, McDonagh AJG.

No. 44  Cost-effectiveness of cell salvage and alternative methods of minimising perioperative allogeneic blood transfusion: a systematic review and economic model.

No. 45  Clinical effectiveness and cost-effectiveness of laparoscopic surgery for colorectal cancer: systematic reviews and economic evaluation.

No. 46  Etanercept and efalizumab for the treatment of psoriasis: a systematic review.

No. 47  Systematic reviews of clinical decision tools for acute abdominal pain.

No. 48  Evaluation of the ventricular assist device programme in the UK.

No. 50  Aminoacetone results: investigation of anxiety. The ANX trial.

Volume 11, 2007

No. 1  Pemetrexed disodium for the treatment of malignant pleural mesothelioma: a systematic review and economic evaluation.

No. 2  A systematic review and economic model of the clinical effectiveness and cost-effectiveness of docetaxel in combination with prednisone or prednisolone for the treatment of hormone-refractory metastatic prostate cancer.

No. 3  A systematic review of rapid diagnostic tests for the detection of tuberculosis infection.

No. 4  The clinical effectiveness and cost-effectiveness of strontium ranelate for the prevention of osteoporotic fragility fractures in postmenopausal women.
By Stevenson M, Davis S, Lloyd-Jones M, Beverley C.
No. 5  
A systematic review of quantitative and qualitative research on the role and effectiveness of written information available to patients about individual medicines.  

No. 6  
Oral naltrexone as a treatment for relapse prevention in formerly opioid-dependent drug users: a systematic review and economic evaluation.  

No. 7  
Glucocorticoid-induced osteoporosis: a systematic review and cost-utility analysis.  
By Kanis JA, Stevenson M, McCloskey EV, Davis S, Lloyd-Jones M.

No. 8  
Epidemiological, social, diagnostic and economic evaluation of population screening for genital chlamydial infection.  

No. 9  
Methadone and buprenorphine for the management of opioid dependence: a systematic review and economic evaluation.  

No. 10  
Exercise Evaluation Randomised Trial (EXERT): a randomised trial comparing GP referral for leisure centre-based exercise, community-based walking and advice only.  

No. 11  
Interferon alfa (pegylated and non-pegylated) and ribavirin for the treatment of mild chronic hepatitis C: a systematic review and economic evaluation.  
By Shepherd J, Jones J, Hartwell D, Davidson P, Price A, Waugh N.

No. 12  
Systematic review and economic evaluation of bevacizumab and cetuximab for the treatment of metastatic colorectal cancer.  
By Tappenden P, Jones R, Paisley S, Carroll C.

No. 13  
A systematic review and economic evaluation of epoetin alfa, epoetin beta and darbepoetin alfa in anaemia associated with cancer, especially that attributable to cancer treatment.  

No. 14  
A systematic review and economic evaluation of statins for the prevention of coronary events.  

No. 15  
A systematic review of the effectiveness and cost-effectiveness of different models of community-based respite care for frail older people and their carers.  

No. 16  
Additional therapy for young children with spastic cerebral palsy: a randomised controlled trial.  
By Weindling AM, Cunningham CC, Glenn SM, Edwards RT, Reeves DJ.

No. 17  
Screening for type 2 diabetes: literature review and economic modelling.  

No. 18  
The effectiveness and cost-effectiveness of cinacalcet for secondary hyperparathyroidism in end-stage renal disease patients on dialysis: a systematic review and economic evaluation.  

No. 19  
The clinical effectiveness and cost-effectiveness of gemcitabine for metastatic breast cancer: a systematic review and economic evaluation.  
By Takeda AL, Jones J, Loveman E, Tan SC, Clegg AJ.

No. 20  
A systematic review of duplex ultrasound, magnetic resonance angiography and computed tomography angiography for the diagnosis and assessment of symptomatic, lower limb peripheral arterial disease.  

No. 21  
The clinical effectiveness and cost-effectiveness of treatments for children with idiopathic steroid-resistant nephrotic syndrome: a systematic review.  
By Colquitt JL, Kirby J, Green C, Cooper K, Trompeter RS.

No. 22  
A systematic review of the routine monitoring of growth in children of primary school age to identify growth-related conditions.  

No. 23  
Systematic review of the effectiveness of preventing and treating Staphylococcus aureus carriage in reducing peritoneal catheter-related infections.  

No. 24  
The clinical effectiveness and cost of repetitive transcranial magnetic stimulation versus electroconvulsive therapy in severe depression: a multicentre pragmatic randomised controlled trial and economic analysis.  

No. 25  
A randomised controlled trial and economic evaluation of direct versus indirect and individual versus group modes of speech and language therapy for children with primary language impairment.  
By Boyle J, McCartney E, Forbes J, O’Hare A.

No. 26  
Hormonal therapies for early breast cancer: systematic review and economic evaluation.  
By Hind D, Ward S, De Nigris E, Simpson E, Carroll C, Wyld L.

No. 27  
Cardioprotection against the toxic effects of anthracyclines given to children with cancer: a systematic review.  
By Bryant J, Picot J, Levitt G, Sullivan I, Baxter L, Clegg A.

No. 28  
Adalimumab, etanercept and infliximab for the treatment of ankylosing spondylitis: a systematic review and economic evaluation.  
No. 29  Prenatal screening and treatment strategies to prevent group B streptococcal and other bacterial infections in early infancy: cost-effectiveness and expected value of information analyses.

No. 30  Clinical effectiveness and cost-effectiveness of bone morphogenetic proteins in the non-healing of fractures and spinal fusion: a systematic review.

No. 31  A randomised controlled trial of postoperative radiotherapy following breast-conserving surgery in a minimum-risk older population. The PRIME trial.

No. 32  Current practice, accuracy, effectiveness and cost-effectiveness of the school entry hearing screen.

No. 33  The clinical effectiveness and cost-effectiveness of inhaled insulin in diabetes mellitus: a systematic review and economic evaluation.
   By Black C, Cummins E, Royle P, Philip S, Waugh N.

No. 34  Surveillance of cirrhosis for hepatocellular carcinoma: systematic review and economic analysis.

No. 35  The Birmingham Rehabilitation Uptake Maximisation Study (BRUM): Home-based compared with hospital-based cardiac rehabilitation in a multi-ethnic population: cost-effectiveness and patient adherence.

No. 36  A systematic review of the clinical, public health and cost-effectiveness of rapid diagnostic tests for the detection and identification of bacterial intestinal pathogens in faeces and food.

No. 37  A randomised controlled trial examining the longer-term outcomes of standard versus new antiepileptic drugs. The SANAD trial.

No. 38  Clinical effectiveness and cost-effectiveness of different models of managing long-term oral anticoagulation therapy: a systematic review and economic modelling.

No. 39  A systematic review and economic model of the clinical effectiveness and cost-effectiveness of interventions for preventing relapse in people with bipolar disorder.

No. 40  Taxanes for the adjuvant treatment of early breast cancer: systematic review and economic evaluation.
   By Ward S, Simpson E, Davis S, Hind D, Rees A, Wilkinson A.

No. 41  The clinical effectiveness and cost-effectiveness of screening for open angle glaucoma: a systematic review and economic evaluation.

No. 42  Acceptability, benefit and costs of early screening for hearing disability: a study of potential screening tests and models.
   By Davis A, Smith P, Ferguson M, Stephens D, Gianopoulos I.

No. 43  Contamination in trials of educational interventions.

No. 44  Overview of the clinical effectiveness of positron emission tomography imaging in selected cancers.
   By Facey K, Bradbury I, Laking G, Payne E.

No. 45  The effectiveness and cost-effectiveness of carmustine implants and temozolomide for the treatment of newly diagnosed high-grade glioma: a systematic review and economic evaluation.

No. 46  Drug-eluting stents: a systematic review and economic evaluation.

No. 47  The clinical effectiveness and cost-effectiveness of cardiac resynchronisation (biventricular pacing) for heart failure: systematic review and economic model.

No. 48  Recruitment to randomised trials: strategies for trial enrolment and participation study. The STEPS study.
   By Campbell MK, Snowdon C, Francis D, Elbourne D, McDonald AM, Knight R, et al.

No. 49  Cost-effectiveness of functional cardiac testing in the diagnosis and management of coronary artery disease: a randomised controlled trial. The CECaT trial.

No. 50  Evaluation of diagnostic tests when there is no gold standard. A review of methods.
   By Rutjes AWS, Reitama JB, Coomarasamy A, Khan KS, Bossuyt PMM.

No. 51  Systematic reviews of the clinical effectiveness and cost-effectiveness of proton pump inhibitors in acute upper gastrointestinal bleeding.

No. 52  A review and critique of modelling in prioritising and designing screening programmes.

No. 53  An assessment of the impact of the NHS Health Technology Assessment Programme.
   By Hannay S, Buxton M, Green C, Coulson D, Raftery J.

Volume 12, 2008

No. 1  A systematic review and economic model of switching from non-glycopeptide to glycopeptide antibiotic prophylaxis for surgery.
No. 2  'Cut down to quit' with nicotine replacement therapies in smoking cessation: a systematic review of effectiveness and economic analysis.
By Wang D, Connock M, Barton P, Fry-Smith A, Aveyard P, Moore D.

No. 3  A systematic review of the effectiveness of strategies for reducing fracture risk in children with juvenile idiopathic arthritis with additional data on long-term risk of fracture and cost of disease management.

No. 4  Does befriending by trained lay workers improve psychological well-being and quality of life for carers of people with dementia, and at what cost? A randomised controlled trial.
By Charlesworth G, Shepstone L, Wilson E, Thalanany M, Mugford M, Poland F.

No. 5  A multi-centre retrospective cohort study comparing the efficacy, safety and cost-effectiveness of hysterectomy and uterine artery embolisation for the treatment of symptomatic uterine fibroids. The HOPEFUL study.

No. 6  Methods of prediction and prevention of pre-eclampsia: systematic reviews of accuracy and effectiveness literature with economic modelling.

No. 7  The use of economic evaluations in NHS decision-making: a review and empirical investigation.
By Williams I, Melver S, Moore D, Bryan S.

No. 8  Stapled haemorrhoidectomy (haemorrhoidopexy) for the treatment of haemorrhoids: a systematic review and economic evaluation.

No. 9  The clinical effectiveness of diabetes education models for Type 2 diabetes: a systematic review.
By Loveman E, Frampton GK, Clegg AJ.

No. 10  Payment to healthcare professionals for patient recruitment to trials: systematic review and qualitative study.
By Rafferty J, Bryant J, Powell J, Kerr C, Hawker S.

No. 11  Cyclooxygenase-2 selective non-steroidal anti-inflammatory drugs (etodolac, meloxicam, celecoxib, rofecoxib, etoricoxib, valdecoxib and lumiracoxib) for osteoarthritis and rheumatoid arthritis: a systematic review and economic evaluation.

No. 12  The clinical effectiveness and cost-effectiveness of central venous catheters treated with anti-infective agents in preventing bloodstream infections: a systematic review and economic evaluation.

No. 13  Stepped treatment of older adults on laxatives. The STOOL trial.

No. 14  A randomised controlled trial of cognitive behaviour therapy in adolescents with major depression treated by selective serotonin reuptake inhibitors. The ADAPT trial.

No. 15  The use of irinotecan, oxaliplatin and raltitrexed for the treatment of advanced colorectal cancer: systematic review and economic evaluation.
By Hind D, Tappenden P, Tumur I, Eggington E, Sutchife P, Ryan A.

No. 16  Ranibizumab and pegaptanib for the treatment of age-related macular degeneration: a systematic review and economic evaluation.

No. 17  Systematic review of the clinical effectiveness and cost-effectiveness of 64-slice or higher computed tomography angiography as an alternative to invasive coronary angiography in the investigation of coronary artery disease.

No. 18  Structural neuroimaging in psychosis: a systematic review and economic evaluation.

No. 19  Systematic review and economic analysis of the comparative effectiveness of different inhaled corticosteroids and their usage with long-acting beta2 agonists for the treatment of chronic asthma in adults and children aged 12 years and over.

No. 20  Systematic review and economic analysis of the comparative effectiveness of different inhaled corticosteroids and their usage with long-acting beta2 agonists for the treatment of chronic asthma in children under the age of 12 years.

No. 21  Ezetimibe for the treatment of hypercholesterolaemia: a systematic review and economic evaluation.

No. 22  Topical or oral ibuprofen for chronic knee pain in older people. The TOB study.

No. 23  A prospective randomised comparison of minor surgery in primary and secondary care. The MiSTIC trial.

No. 24  A review and critical appraisal of measures of therapist–patient interactions in mental health settings.

No. 25  The clinical effectiveness and cost-effectiveness of screening programmes for amblyopia and strabismus in children up to the age of 4–5 years: a systematic review and economic evaluation.
By Carlton J, Karon J, Czoski-Murray C, Smith KJ, Marr J.
| No. 26 | A systematic review of the clinical effectiveness and cost-effectiveness and economic modelling of minimal incision total hip replacement approaches in the management of arthritic disease of the hip.  
| No. 27 | A preliminary model-based assessment of the cost–utility of a screening programme for early age-related macular degeneration.  
| No. 28 | Intravenous magnesium sulphate and sotalol for prevention of atrial fibrillation after coronary artery bypass surgery: a systematic review and economic evaluation.  
By Shepherd J, Jones J, Frampton GK, Tanajewski L, Turner D, Price A. |
| No. 29 | Absorbent products for urinary/faecal incontinence: a comparative evaluation of key product categories.  
| No. 30 | A systematic review of repetitive functional task practice with modelling of resource use, costs and effectiveness.  
Prioritisation Strategy Group

Members

Chair, 
Professor Tom Walley, 
Director, NHS HTA Programme, 
Department of Pharmacology & 
Therapeutics, 
University of Liverpool 
Dr Edmund Jessop, Medical Adviser, National Specialist, Commissioning Advisory Group (NS-CAG), Department of Health, London 
Professor Jon Nicholl, Director, Medical Care Research Unit, University of Sheffield, School of Health and Related Research 
Dr Ron Zimmern, Director, Public Health Genetics Unit, Strangeways Research Laboratories, Cambridge

Professor Bruce Campbell, Consultant Vascular & General Surgeon, Royal Devon & Exeter Hospital 
Professor Robin E Ferner, Consultant Physician and Director, West Midlands Centre for Adverse Drug Reactions, City Hospital NHS Trust, Birmingham

Members

Dr Jeffrey Aronson, Reader in Clinical Pharmacology, Department of Clinical Pharmacology, Radcliffe Infirmary, Oxford 
Professor Jon Deeks, Professor of Health Statistics, University of Birmingham

Director, 
Professor Tom Walley, 
Director, NHS HTA Programme, 
Department of Pharmacology & 
Therapeutics, 
University of Liverpool 
Deputy Director, 
Professor Jon Nicholl, 
Director, Medical Care Research Unit, University of Sheffield, School of Health and Related Research

Programme Director, 
Professor Tom Walley, 
Director, NHS HTA Programme, 
Department of Pharmacology & 
Therapeutics, 
University of Liverpool 
Professor Deborah Ashby, Professor of Medical Statistics, Department of Environmental and Preventative Medicine, Queen Mary University of London 
Professor Ann Bowling, Professor of Health Services Research, Primary Care and Population Studies, University College London 
Professor John Cairns, Professor of Health Economics, Public Health Policy, London School of Hygiene and Tropical Medicine, London 
Professor Nicky Callum, Director of Centre for Evidence Based Nursing, Department of Health Sciences, University of York

Chairs, 
Professor Jon Nicholl, 
Director, Medical Care Research Unit, University of Sheffield, School of Health and Related Research 
Dr Andrew Farmer, University Lecturer in General Practice, Department of Primary Health Care, University of Oxford 
Professor Deborah Ashby, Professor of Medical Statistics, Department of Environmental and Preventative Medicine, Queen Mary University of London 
Professor Ann Bowling, Professor of Health Services Research, Primary Care and Population Studies, University College London 
Professor John Cairns, Professor of Health Economics, Public Health Policy, London School of Hygiene and Tropical Medicine, London 
Professor Nicky Callum, Director of Centre for Evidence Based Nursing, Department of Health Sciences, University of York

Deputy Chair, 
Dr Andrew Farmer, 
University Lecturer in General Practice, Department of Primary Health Care, University of Oxford 

Dr Linda Patterson, Consultant Physician, Department of Medicine, Barnsley General Hospital 
Professor Hywel Williams, Professor of Dermato-Epidemiology, University of Nottingham

Current and past membership details of all HTA ‘committees’ are available from the HTA website (www.hta.ac.uk)

Current and past membership details of all HTA ‘committees’ are available from the HTA website (www.hta.ac.uk)
How to obtain copies of this and other HTA Programme reports.

An electronic version of this publication, in Adobe Acrobat format, is available for downloading free of charge for personal use from the HTA website (http://www.hta.ac.uk). A fully searchable CD-ROM is also available (see below).

Printed copies of HTA monographs cost £20 each (post and packing free in the UK) to both public and private sector purchasers from our Despatch Agents.

Non-UK purchasers will have to pay a small fee for post and packing. For European countries the cost is £2 per monograph and for the rest of the world £3 per monograph.

You can order HTA monographs from our Despatch Agents:

– fax (with credit card or official purchase order)
– post (with credit card or official purchase order or cheque)
– phone during office hours (credit card only).

Additionally the HTA website allows you either to pay securely by credit card or to print out your order and then post or fax it.

Contact details are as follows:

HTA Despatch
Email: orders@hta.ac.uk
c/o Direct Mail Works Ltd
Tel: 02392 492 000
4 Oakwood Business Centre
Fax: 02392 478 555
Downley, HAVANT PO9 2NP, UK
Fax from outside the UK: +44 2392 478 555

NHS libraries can subscribe free of charge. Public libraries can subscribe at a very reduced cost of £100 for each volume (normally comprising 30–40 titles). The commercial subscription rate is £300 per volume. Please see our website for details. Subscriptions can only be purchased for the current or forthcoming volume.

Payment methods

Paying by cheque
If you pay by cheque, the cheque must be in pounds sterling, made payable to Direct Mail Works Ltd and drawn on a bank with a UK address.

Paying by credit card
The following cards are accepted by phone, fax, post or via the website ordering pages: Delta, Eurocard, Mastercard, Solo, Switch and Visa. We advise against sending credit card details in a plain email.

Paying by official purchase order
You can post or fax these, but they must be from public bodies (i.e. NHS or universities) within the UK. We cannot at present accept purchase orders from commercial companies or from outside the UK.

How do I get a copy of HTA on CD?

Please use the form on the HTA website (www.hta.ac.uk/htacd.htm). Or contact Direct Mail Works (see contact details above) by email, post, fax or phone. HTA on CD is currently free of charge worldwide.

The website also provides information about the HTA Programme and lists the membership of the various committees.
A preliminary model-based assessment of the cost–utility of a screening programme for early age-related macular degeneration

J Karnon, C Czoski-Murray, K Smith, C Brand, U Chakravarthy, S Davis, N Bansback, C Beverley, A Bird, S Harding, I Chisholm and YC Yang

June 2008
