23 **A brief review on frictional pressure drop reduction studies for laminar and turbulent**  
24 **flow in helically coiled tubes**

25

26 **Abstract**

27

28 This review, summarises the pertinent literature on drag reduction (DR) in laminar and  
29 turbulent flow in coiled tubes. Due to their compact design, ease of manufacture and superior  
30 fluid mixing properties, helically coiled tubes are widely used in numerous industries.  
31 However, flow through coiled tubes yields enhanced frictional pressure drops and thus, drag  
32 reduction is desirable as it can: decrease the system energy consumption, increase the flow  
33 rate and reduce the pipe and pump size. The main findings and correlations for the friction  
34 factor are summarised for drag reduction with the: injection of air bubbles and addition of  
35 surfactant and polymer additives. The purpose of this study is to provide researchers in  
36 academia and industry with a concise and practical summary of the relevant correlations and  
37 supporting theory for the calculation of the frictional pressure drop with drag reducing  
38 additives in coiled tubes. A significant scope for future research has also been identified in  
39 the fields of: air bubble and polymer drag reduction techniques.

40

41 **Keywords:** Helically coiled tube, drag reduction, frictional pressure drop, surfactants,  
42 polymer solutions.

43

44 **1. Introduction**

45

46 Due to their compact design, ease of manufacture and high efficiency in heat and  
47 mass transfer, helically coiled tubes are widely used in a number of industries and processes  
48 such as in the food, nuclear, aerospace and power generation industries and in heat recovery,  
49 refrigeration, space heating and air-conditioning processes. Due to the formation of a  
50 secondary flow, which inherently enhances the mixing of the fluid, helically coiled tube heat  
51 exchangers are known to yield improved heat transfer characteristics when compared to  
52 straight tube heat exchangers. The secondary flow, which finds its origins in the centrifugal  
53 force, is perpendicular to the axial fluid direction and reduces the thickness of the thermal  
54 boundary layer. However, for single and multiphase flows, the secondary flow yields a  
55 substantial increase in the frictional pressure drop, which often results in diminished system  
56 efficiencies (due to enhanced pumping power requirements). For air-water two-phase bubbly  
57 flow in helically coiled tubes, Akagawa *et al.* (1971) reported frictional pressure drops in the  
58 range of

59

60

61 **Figure 1: Schematic representation of helical pipe characteristics.**

62 1.1 to 1.5 times greater than those in straight tubes, *ceteris paribus*, whilst, with the use of  
 63 nanofluids, such a penalty could nullify the enhanced efficiencies gained with the dispersion  
 64 of nanoparticles in the base fluid (Aly, 2014). Moreover, due to the secondary flow, the flow  
 65 characteristics are significantly different to those in straight tubes. Whereas in straight tubes  
 66 the transition from laminar to turbulent flow occurs at Reynolds numbers in the region of  
 67 2500, the transition in curved tubes takes place at higher Reynolds numbers. The critical  
 68 Reynolds number (Eq. (1)) is used to determine the transition of the flow from laminar to  
 69 turbulent flow (Ito, 1959).

70

$$71 \quad Re_{crit} = 2E4\delta^{0.32} \quad (1)$$

72

73 where  $\delta$  is the curvature ratio defined through Eq. (2).

74

$$75 \quad \delta = \frac{d_t}{D_c} \quad (2)$$

76

77 For  $\delta^l < 8.6E2$  whilst for  $\delta^l > 8.6E2$ ,  $Re_{crit}$  for a curved tube is equal to that for a straight  
 78 pipe.

79

80 Another dimensionless number, unique to coiled tubes, is the Dean number, given in  
 81 Eq. (3). It is used to characterise the flow in curved tubes and quantifies the magnitude of the  
 82 secondary flow due to the centrifugal force (Mohammed and Narrein, 2012).

83

$$84 \quad De = Re\sqrt{\delta} \quad (3)$$

85

86 The performance of coiled tubes is a complex function of the coil design parameters  
 87 (Fig. 1) as well as the resultant pressure drop. Therefore, drag reduction (DR) techniques  
 88 could be particularly beneficial for systems with curved tubes. Intriguingly, whilst numerous  
 89 investigations have been reported on DR in straight channels and pipelines with the: injection  
 90 of air bubbles (Nouri *et al.*, 2013; Fujiwara *et al.*, 2004), dispersion of surfactants (Gasljevic  
 91 and Matthys, 1997) and polymers (Wei and Willmarth, 1992; Al-Sarkhi and Hanratty, 2001),  
 92 there is a paucity of research in the field of curved tubes. Moreover, researchers have  
 93 reviewed the frictional DR techniques in straight channels and pipes (Merkle and Deutsch,  
 94 1992; Al-Sarkhi, 2010; Murai, 2014) whilst the sole study that reviewed DR in curved tubes  
 95 was presented by Broniarz-Press *et al.* (2007). However, the latter focussed on the application  
 96 of DR surfactant and polymer additives and hence, did not provide a holistic review of the  
 97 relevant studies. The aim of the current study is to critically review the experimental and  
 98 numerical studies done on DR in single-phase (water) laminar and turbulent flow through  
 99 coiled tubes. Such studies are categorized in three sections, representing the pertinent  
 100 techniques reported. Moreover, this paper complements the earlier review undertaken by the  
 101 authors of the present study (Fsadni and Whitty, 2016), as it further elucidates the  
 102 underpinning physics of air-water bubbly flow through curved tubes. It is the authors' hope  
 103 that this review will be useful to both academics and industry based engineers through the  
 104 provision of a concise report on the relevant current knowledge.

105

## 106 **2. Injection of air bubbles**

107

108 Over the past 40 years, the injection of microbubbles in the turbulent boundary layer  
 109 has been investigated by numerous investigators, with the first study reported by McCormick

110 and Bhattacharyya (1973) who investigated the DR to a submersible hull. As summarised in  
 111 Table 1, Shatat *et al.* (2009a&b) were the first to investigate DR with the injection of air  
 112 bubbles in laminar and turbulent low through helically coiled tubes. They reported a  
 113 diminished DR efficiency (Eq. (4)) over that of straight tubes. Such results were more  
 114 significant with higher curvature ratios whilst, the DR increased with higher air volumetric  
 115 void fractions ( $VF$ ) and decreased with higher  $Re$  numbers (Fig. 2). Moreover, DR was  
 116 limited to turbulent flow. Similar results were reported by Saffari *et al.* (2013) who measured  
 117 a 25% DR at a  $VF$  of 0.09 in turbulent flow bubbly flow. The latter study did not investigate  
 118 the DR with straight tubes. However, their experimental parameters are comparable to those  
 119 used by Nouri *et al.* (2013) who reported a DR of 35% for a  $VF$  of 0.09 in straight tubes.

$$120 \quad DR = 100 \left( \frac{f_l - f_{tp}}{f_l} \right) \quad (4)$$

121

122 where  $f_l$  is the Fanning friction factor for single-phase flow and  $f_{tp}$  is the friction factor for  
 123 two-phase flow.

124

125 For a straight vertical pipe, Fujiwara *et al.* (2004) reported that, with a high  $VF$  in the  
 126 near-wall region, the turbulence intensity and Reynolds stress are reduced in a wide region of  
 127 the pipe. The turbulence energy dissipation occurs around the bubbles due to bubble-induced  
 128 eddies, whilst the diminished fluid density in the near-wall region reduces the shear stress,  
 129 thus resulting in a lower system frictional pressure drop. Saffari *et al.* (2013) reported that in  
 130 curved tubes, higher  $Re$  numbers and curvature ratios, result in larger centrifugal forces  
 131 which force the lower density phase (air bubbles) to migrate towards the inner tube wall  
 132 region. Resultantly, the shear stress at the inner tube wall region is lower than that at the outer  
 133 wall region. Hence, the uneven distribution of the air bubbles at higher  $Re$  numbers and  
 134 curvature ratios results in a diminished DR efficiency.

135

136

137 **Figure 2: DR as a function of the air  $VF$  ( $\alpha$ ) for a curvature ratio of 0.025 (Shatat *et al.*, 2009a. Fig. 11).**

138

139 These studies are in a general agreement with relevant theory and numerous DR  
 140 studies reported for channel and straight tube flow. Moreover, there is significant scope for  
 further research in DR (in coiled tubes) as a function of the bubble diameter. In fact, for

141 straight tubes and channels, some controversy surrounds the impact of bubble size on the DR,  
 142 where some investigators reported the DR to be a strong function of the bubble diameter (Liu  
 143 1993; Murai *et al.*, 2007) while other investigators reported the DR to be independent of the  
 144 bubble diameter (Moriguchi and Kato, 2002; Shen *et al.*, 2006). The relation of the bubble  
 145 induced DR studies with those reviewed for two-phase gas-liquid frictional pressure drop  
 146 characteristics in coiled tubes (Fsadni and Whitty, 2016) remains indeterminate. In fact, the  
 147 latter investigations reported a general agreement with the Lockhart and Martinelli  
 148 correlation for straight tubes, with the two-phase frictional pressure drop multiplier in excess  
 149 of unity.

150

### 151 3. Surfactant additives

152

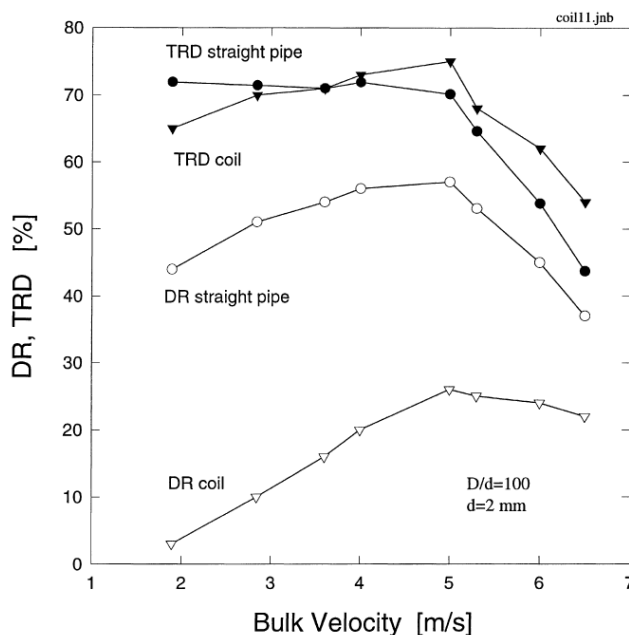

153 Surface-active agents (surfactants) are low molecular weight, viscous, non-polymer,  
 154 water-based chemicals that tend to accumulate at a surface and diminish interactive forces  
 155 between the molecules of the base fluid, thus reducing the surface tension. Inaba *et al.* (2005)  
 156 reported that surfactant additives form a network structure of rod-like micelles which absorbs  
 157 the turbulent energy with its flexibility and deformation, thus leading to a flow laminarisation  
 158 effect. Hence, surfactants enhance the elastic properties of the fluid with the resultant  
 159 increase in DR. Unlike polymer based fluids, the mechanical degradation of the micelle  
 160 network at high shear stresses is completely reversed at a low flow rate. All the studies  
 161 reviewed reported a DR limited to the transition and turbulent flows, with a reduced DR in  
 162 curved tubes when compared to straight tubes, *ceteris paribus*. Such findings were attributed  
 163 to the formation of the secondary flow which is largely unaffected by the surfactant additive.  
 164 Gasljevic and Matthys (1999) reported that for a velocity range of 2-5m/s, the secondary flow  
 165 effects were separated from the turbulence effects through the use of the turbulence reduction  
 166 – drag (TRD) method given in Eq. (5). This yielded a TDR of 70% (turbulence suppression)  
 167 for both coiled and straight tubes (Fig. 3). In contrast, Broniarz-Press *et al.* (2003) reported  
 168 that the tube curvature effect on the friction factor was diminished due to the damping of the  
 169 secondary flows streams. A broad analogy can be made with nanofluid flow in coiled tubes  
 170 where, nanoparticles were also attributed to the mitigation of the secondary flow (Fsadni and  
 171 Whitty, 2016).

172

$$173 \quad TRD = \frac{FC_{bf,tb} - FC_{DRF}}{FC_{bf,tb} - FC_{bf,lm}} \quad (5)$$

174

175 where *lm* refers to the laminar flow of the base fluid (without the DR additives) at the same  
 176 *Re* number and *tb* refers to the turbulent flow of the base fluid.

177

178 **Figure 3: Friction reduction in terms of DR and TRD for a coiled and straight pipe (Gasljevic and**  
 179 **Matthys, 1999 Fig. 4).**

180 At laminar flow conditions, Weber *et al.* (1991) and Gasljevic and Matthys (2009)  
 181 reported an increase in the frictional pressure drop (compared to water). This was attributed  
 182 to the enhanced solution viscosity. There is a general agreement amongst the studies  
 183 reviewed that lower coil curvatures and higher surfactant concentrations yielded higher DR  
 184 efficiencies. Moreover, Kamel and Shah (2013) reported that at higher concentrations,  
 185 surfactant solutions are more resistant to mechanical degradation and hence, yield higher DR  
 186 efficiencies at increased  $Re$  numbers. Therefore, Broniarz-Press *et al.* (2002) reported that  
 187 DR is a strong function of the surfactant concentration, with DR evident above a critical  
 188 concentration. Inaba *et al.* (2005) reported that the dynamic nature of surfactant DR additives  
 189 render them particularly relevant for heating systems. However, such comments should be  
 190 considered in light of the fact that these additives are known to yield reduced heat transfer  
 191 coefficients. Kostic (1994) attributed this phenomenon to the non-homogenous turbulence  
 192 resulting from the flow-induced anisotropy of the highly structured micelle network.  
 193 Weber *et al.* (1991), Inaba *et al.* (2000&2005), Aly *et al.* (2006) and Kamel and Shah (2013)  
 194 presented correlations for the calculation of the friction factor in surfactant solutions. Due to  
 195 the Non-Newtonian properties of these solutions ( $C > 3,000$  ppm), correlations were developed  
 196 as a function of the modified or generalised  $Re$  and  $De$  numbers.

197

#### 198 4. Polymers additives

199

200 Toms (1948) reported that the addition of minute concentrations of high-molecular  
 201 weight, long chain and flexible polymers to a Newtonian solvent can yield significant DR  
 202 properties. Whilst it is widely accepted that the DR efficiency is a strong function molecular  
 203 weight and distribution, molecular structure and solubility, the underpinning physics are  
 204 known to be complex and not well-understood (Gallego and Shah, 2009). Factors such as  
 205 shear thinning, viscoelasticity and molecular stretching have been suggested to diminish the  
 206 turbulence in the fluid (Bird *et al.*, 1987), thus resulting in DR.

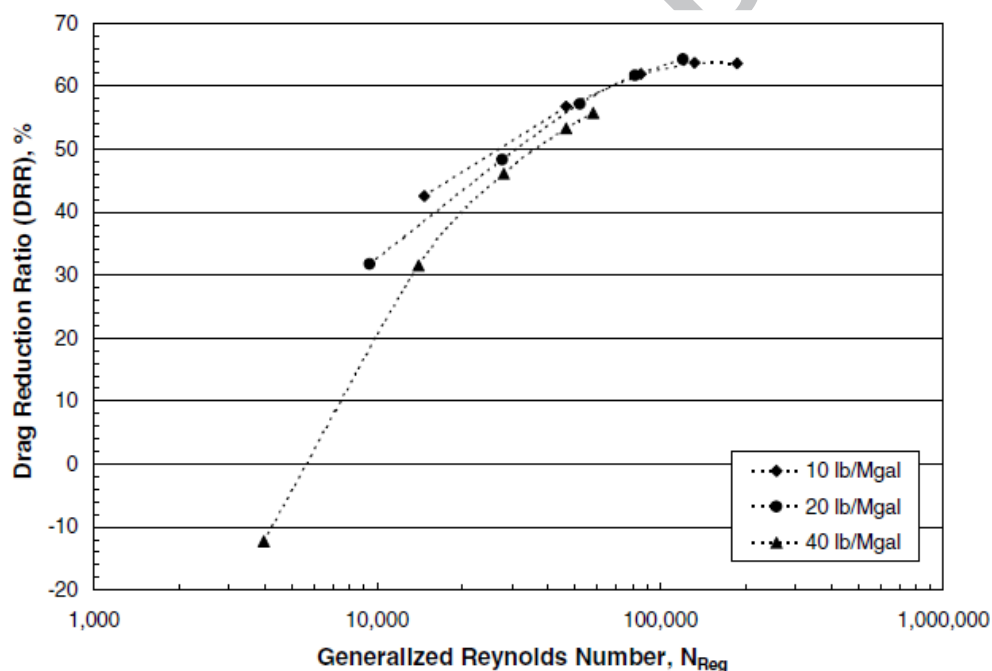

207 Shah and Zhou (2001) stated that the DR mechanism of polymers occurs at the  
 208 boundary layer and therefore is typically more effective in smaller tube diameters. Moreover,

209 in agreement with the findings reported for air-bubble injection, DR efficiency decreases with  
 210 higher coil curvatures. This is inherent to the effects of the centrifugal force on the fluid  
 211 flow. DR is also a function of the ability of the polymer to resist thermal and mechanical  
 212 degradation. Shah *et al.* (2006) reported that at a volume concentration of 0.07%, the widely  
 213 used partially hydrolysed polyacrylamide (PHPA) copolymer (Nalco ASP-820) yielded the  
 214 highest DR (65%). At this concentration, it was assumed that the fluid behaviour is quasi-  
 215 Newtonian. This concentration was subsequently used by Gallego and Shah (2009) and  
 216 Ahmed Kamel (2011). Gallego and Shah presented a unique generalised friction pressure  
 217 correlation for DR polymer solutions in coiled tubes. Their correlation assumed that the  
 218 appropriate characteristic polymer solution viscosity is relative to the zero shear rate  
 219 viscosity, that is, the shear stress required to deform the polymer molecule from its  
 220 equilibrium state.

221 The effect of the polymer concentration is also function of the specific physical  
 222 conditions of the flow. Resultantly, Shah and Zhou (2001) reported that for large tubes and  
 223 low flow rates, high concentrations of polymer additives increased the fluid drag and delayed  
 224 the onset of DR (Fig. 4). For small diameter tubes, the opposite effect was reported and thus,  
 225 a higher polymer concentration increased the DR.

226

227

228

Figure 4: Effect of polymer concentration (Xanthan) on DR ratio (Shah and Zhou, 2001 Fig. 5).

229 The effect of elevated temperatures on the DR of polymers in coiled tubes was  
 230 investigated by Gallego and Shah (2009) and Ahmed Kamel (2011) who reported that, in  
 231 contrast to the findings for straight tubes, DR remained quasi-constant (Ahmed Kamel) or  
 232 increased (Gallego and Shah) with temperature. It is widely accepted that with polymer  
 233 solutions in straight tubes, elevated temperatures yield a drop in the DR. This is due to a  
 234 combination of factors, such as the deterioration of the solvent-polymer interaction and the  
 235 diminishing of the macromolecule size (Clifford and Sorbie, 1985; Nesyn *et al.*, 1989). In  
 236 view of this complexity and the paucity of studies for curved tubes, Gallego and Shah (2009)  
 237 and Ahmed Kamel (2011) concluded that the origins of their results are indeterminate and  
 238 thus require further investigation. In contrast to the numerous studies on polymer DR  
 239 additives to gas-liquid flows in straight tubes (Sylvester and Brill, 1976; Al-Sarkhi and

240 Soleimani, 2004), there are no related studies for coiled tubes. This presents further scope for  
 241 future research in the field of two-phase flow in coiled tubes.

244

245 **5. Conclusions**

246

247 The studies reviewed have demonstrated that, due to the secondary flow, which  
 248 increases with curvature, DR in coiled tubes is diminished when compared to straight tubes.  
 249 However, a significant DR can be still be achieved with the introduction of: bubbles (9-25%),  
 250 surfactant (30-59%) and polymer (circa 30-80%) additives. DR is a strong function of the  
 251 surfactant concentration and the air volume fraction whilst with polymer additives DR  
 252 efficiency is dependent on the molecular weight, structure and solubility. DR is generally  
 253 present in flows with  $Re$  numbers in excess of the critical number. However, at elevated  $Re$   
 254 numbers DR diminishes. This is due to the higher centrifugal forces (air bubbles and  
 255 polymers) and mechanical degradation with high shear stress (surfactants). A number of  
 256 authors have presented correlations for the calculation of the friction factor which are  
 257 typically a function of the: curvature ratio,  $Re$  and  $De$  numbers and the additive  
 258 concentration.

259 Due to their low molecular weights, viscous properties and resilience to mechanical  
 260 degradation, surfactant based fluids are generally considered to be superior to polymer based  
 261 fluids. Hence, surfactants are suitable for a variety of applications such as district cooling and  
 262 heating systems. A significant scope for future research has been elucidated for DR in coiled  
 263 tubes with the injection of air bubbles (impact of bubble size and relation with the Lockhart  
 264 and Martinelli correlation) and the application of a combination of methods, such as the use  
 265 of polymer and surfactant additives with bubbly flow.

## 267 Acknowledgments

268  
 269 The authors of the current investigation would like to thank the University of Central  
 270 Lancashire UK, for facilitating the completion of this study as well as the various authors  
 271 who have been contacted during the course of this study.

## 273 Notation List

|     |           |  |
|-----|-----------|--|
| 274 |           |  |
| 275 | $C$       | concentration (ppm)  |
| 276 | $C_c$     | non-dimensional surfactant concentration (-)                   |
| 277 | $C_{st}$  | empirical constant (-)   |
| 278 | $d$       | tube internal diameter (m)                                     |
| 279 | $dr$      | drag ratio (-)   |
| 280 | $D$       | helix diameter (m)   |
| 281 | $De$      | Dean number ( $Re\delta^{1/2}$ ) (-)                           |
| 282 | $De'$     | modified Dean number ( $Re'\delta^{1/2}$ ) (-)                 |
| 283 | $De''$    | modified Dean number ( $Re_{gen}\delta^{1/2}$ ) (-)            |
| 284 | $DR$      | drag reduction (%)   |
| 285 | $f$       | friction factor (-)  |
| 286 | $FC$      | friction coefficient (-)                                       |
| 287 | $G_z$     | Graetz number ( $RePr/z$ ) (-)                                 |
| 288 | $G_z'$    | modified Graetz number ( $Re'Pr'/z$ ) (-)                      |
| 289 | $H$       | pitch (m)  |
| 290 | $K$       | rheometric and technical consistency index ( $\text{Pa s}^n$ ) |
| 291 | $L$       | length (m)   |
| 292 | $ME$      | mean error (%)   |
| 293 | $n$       | power law model flow behaviour index (-)                       |
| 294 | $N$       | number of turns (-)  |
| 295 | $N_{De}$  | Deborah number (-)   |
| 296 | $N_{De}'$ | modified Deborah number (-)                                    |

|     |   |   |
|-----|---|---|
| 297 | $P$   | pressure (Pa)   |
| 298 | $Pr$  | Prandtl number (-)  |
| 299 | $Pr'$   | modified Prandtl number (-)   |
| 300 | $Q$   | volume flow rate (m <sup>3</sup> /s)  |
| 301 | $Re$  | Reynolds number (-)   |
| 302 | $Re'$   | modified Reynolds number as proposed by Metzner and Reed (1955)                     |
| 303 | $\left[8^{1-n} \left(\frac{3n+1}{4n}\right) \left(\frac{v^{2-n} d_t^n \rho}{K}\right)\right]$ | (-)   |
| 304 | $Re_{crit}$   | critical Reynolds number ( $2E4\delta^{0.32}$ ) (-)                                 |
| 305 | $Re_{gen}$  | generalised Reynolds number $\left(\frac{v^{2-n} d_t^n \rho}{8^{n-1} K}\right)$ (-) |
| 306 | $SD$  | standard deviation (%)  |
| 307 | $T$   | temperature (°C)  |
| 308 | $T_c$   | non-dimensional surfactant solution temperature (-)                                 |
| 309 | $TRD$   | turbulence reduction: drag (-)  |
| 310 | $V$   | flow velocity (m/s)   |
| 311 | $VC$  | volume concentration (%)  |
| 312 | $VF$  | volumetric void fraction (-)  |
| 313 | $We$  | Weber number (-)  |
| 314 | $Wi$  | Weissenberg number ( $\sigma_{el}/\sigma_v$ ) (-)                                   |
| 315 | $WC$  | weight concentration (%)  |
| 316 | $x$   | axial distance of coiled pipe (m)   |
| 317 | $z$   | dimensionless axial distance ( $x/d_t$ ) (-)  |

## Highlights

- Review on pressure drop reduction studies in helically coiled tubes
- Air bubbles, surfactant and polymer additives are effective in diminishing drag
- Drag reduction is diminished in relation to straight tubes
- Drag reduction is predominantly evident in turbulent flow
- Drag reduction diminishes with higher coil curvatures and excessive  $Re$  numbers
