50 Abstract

Systemic amyloidosis is caused by deposition of amyloid proteins in varying organ systems throughout the body, leading to dysfunction within those systems. The development of cardiac amyloidosis is one of the main indicators for a poor prognosis for patients. Cardiac amyloidosis is most commonly caused by the Immunoglobulin light chain amyloidosis and the transthyretin amyloidosis. Both have poor prognoses when associated with cardiac amyloidosis, however, the patients with the former subtype fair far worse than those with the later. Despite amyloidosis having a history of being underdiagnosed, recent epidemiological data indicates that the rate of diagnosis has increased which has coincided with an improved in patient median survival rates. It is of great importance that patients are diagnosed with the correct subtype as the main treatment strategy is to treat the underlying cause of the amyloidosis. If a misdiagnosis is made patients can receive treatment that might be ineffective or even harmful. There is a great of progress being made in the pharmacological treatments being made for

64 treating the underlying causes, however, many of the proposed treatments still need more 65 evidence to support its use.

86 **<u>1. Introduction</u>**

87

Systemic amyloidosis is a rare group of diseases caused by the extracellular deposition of amyloid proteins in various tissues throughout the body¹. As of yet more than 30 proteins have been found that can aggregate as an amyloid protein, however, with the use of mass spectrometry it is suspected that there are many more of these precursor proteins².

In the majority of the cases, cardiac amyloidosis (CA) is caused by two common subtypes of these proteins, immunoglobulin light chain (AL) amyloidosis and transthyretin (ATTR) amyloidosis, together accounting for approximately 98% of all cases of CA^{1,3-4}. Not only do AL and ATTR amyloidosis have markedly different prognoses, with a median survival of 6-12 months and 2-6 years respectively, they also have significantly different treatments which is why there is a great emphasis on specifying the subtype of amyloidosis³⁻⁵.

The main focus of this review will revolve around CA as it is the leading cause of morbidity and mortality in systemic amyloidosis regardless of the subtype¹. As it has been shown that the prevalence of CA increases with age, this is of ever greater importance due to the expanding aging population⁶. However, amyloidosis is probably still underdiagnosed and even when diagnosed, the different subtypes with their own specific treatments go unrecognized, which can lead to mismanagement of patients⁷. This emphasises the need of an updated review on CA to familiarise clinicians with the specifics of amyloidosis towards improved patient care².

105

107

106 **<u>2. Pathophysiology</u>**

Amyloidosis is characterised by infiltrative deposits of 'amyloid proteins', which are typically waxy, starch-like deformed protein fibrils⁷. Many different types of causative proteins have been identified, some causing systemic amyloidosis, with deposits in multiple organ systems, and others showing more localised pathology in a specific organ⁸. Some well-known diseases are caused by localised misfolded protein deposits (i.e. localised amyloidosis), such as Alzheimer's 113 disease (Amyloid-ß precursor protein), Creutzfeld-Jakob disease (Prion protein) and familial 114 dementias⁸. Proteins may misfold and form amyloid fibrils if mutations occur in the genetic coding for that protein, causing amino acid substitutions, or if the protein stability is compromised⁵. As 115 with most diseases, factors are hereditary as well as environmental (chemical, electrical, and 116 117 mechanical stimuli)⁷. This review focuses on the amyloidosis types that are most prominent in causing cardiac complications: immunoglobulin amyloidosis (AL), ATTRwt amyloidosis (formerly 118 called senile systemic amyloidosis [SSA]), ATTRv amyloidosis (formerly called familial amyloid 119 polyneuropathy [FAP]), Table 1 provides a summary of each of the above mentioned subtypes⁸. 120

121

123

122 **2.1** Immunoglobulin light chain (AL) amyloidosis:

AL amyloidosis is characterised by a malignant plasma cell clone with a resulting excess of a 124 particular misfolded light- or heavy-chain immunoglobulin (Ig) which is then systemically 125 deposited⁸. The AL subtype is present in about 15% of patients with multiple myeloma (MM). 126 127 however isolated AL amyloidosis (primary AL) has a different pattern of disease and is therefore 128 an alone standing diagnosis⁸. Public Health England classifies primary AL amyloidosis as a 129 cancer, and according to one report, it accounts for 65% of 5-20 per million cases of amyloidosis in the UK⁹. AL amyloidosis can affect multiple organs, or only a single organ, usually the kidney, 130 heart, liver, gut, and peripheral nervous system⁷⁻⁸. The onset is rapid and treatment is targeted at 131 132 the monoclonal immunoglobulin-producing cells⁸. Treatment that reduces the circulating free light 133 chains (FLC) has better outcomes for heart failure, because FLC seems to be toxic to myocardial cells¹⁰. This suggests that Cardiac-related AL amyloidosis (AL-CA) is "not simply an infiltrative 134 cardiomyopathy but rather a toxic infiltrative disorder"¹⁰. 135

136

138

137 2.2 Transthyretin (ATTR) Amyloidosis:

ATTR Amyloidosis caused by misfolded or destabilised transthyretin (TTR)⁷. TTR is produced predominantly by the liver, retinal pigment epithelium and choroid plexus⁸. Two main types of TTR cause CA: a wild-type (AATRwt) and variant-type (ATTRv)⁷⁻⁸. ATTRwt amyloidosis is 142 associated with advancing age (hence the former name 'systemic senile amyloidosis'). The 143 hypothesised mechanism of disease is that TTR, a cyclic tetramer protein in circulation, becomes unstable in elderly patients, and is deposited as pathologic amylaceous (starchy) 144 fibrils⁸. The ATTRv subtype is caused by a 'variant' TTR with altered genetic mutation, inherited 145 146 in an autosomal dominant pattern⁸. The onset may be early, with gradually increasing severity of symptoms over several decades⁸. There are multiple types of mutations, with varying degrees of 147 resultant instability of the TTR tetramer¹¹. The resulting amyloid fibrils are deposited in various 148 systems depending on the mutant type; in peripheral and autonomic nerves, heart, gut, kidney, 149 eves and brain⁸. It was found that mutations associated with greater instability in TTR affected 150 the peripheral nervous and oculo-leptomeningeal systems more frequently, whereas more 151 stable TTR variants showed greater affinity for the cardiac system ¹². 152

153

154

155 **<u>3. Cardiac Amyloidosis (CA)</u>**:

156 Clinical manifestation is dependent upon the type of amyloidosis and the site of its occurrence 157 (Figure 1). The complexity tends to develop due cardiac involvement either as part of a systemic 158 process or a local phenomenon. Surprisingly, it is not the quantity of organ systems affected, but 159 the deposition of amyloid fibrils in the heart that decrees a poor prognosis¹⁰.

160 CA is thought to be underdiagnosed¹³. Early recognition and diagnosis are needed to delay the 161 progression of the disease and increase suitability for surgical interventions¹³. CA should be 162 considered as an important differential in patients with heart failure particularly if ejection fraction 163 is preserved (HFpEF)¹³.

Amyloid deposits may be found in one or all of the heart layers: endo-, myo- and pericardium¹³. The endo-myocardium will be the focus of this literature review and refers to the lining of the four chambers as well as the valves, and the cardiac muscle itself¹³. Though nodular deposits of amyloid may be found on the pericardium¹³, this will not be discussed any further in this review
as it is not discussed at great length in the existing literature.

169 **3.1 Diagnosing:**

At first glance, diagnosing CA seems relatively straight forward. However, some of the difficulties in reaching a timely diagnosis include the rarity of the disease, late presentation of diverse clinical symptoms and the existence of various subtypes¹⁴. CA is also often mistaken for hypertrophic cardiomyopathy with left ventricular outflow tract obstruction (LVOTO)⁷. Thus, a surprise encounter on the operating table is not uncommon but significant advancements in diagnostic methods should decrease such scenarios moving forward¹⁴.

176 3.1.1 Clinical:

Each subtype of amyloidosis has specific symptoms associated with it which are presented in
Figure 2. CA classically presents as a rapidly progressive congestive heart failure in the absence
of ischaemic pathology, which may be accompanied by conduction system disturbances such as
arrhythmias and heart blocks¹⁵.

181 Congestive heart failure due to restrictive cardiomyopathy should be met with high clinical 182 suspicion¹⁵. The amyloidotic heart is firm, rubbery and less compliant due to the replacement of 183 myocytes with amyloid deposits¹⁵. Subsequently cardiac relaxation is impaired, causing an 184 increase in right sided filling pressures. Increased jugular venous pressure, hepatomegaly and 185 peripheral oedema are not uncommon¹⁵.

Patients may complain of exertional dyspnoea, fatigue, and chest discomfort. In severe cases
 cardiac cachexia may also be present^{13,15}.

188 Extra cardiac manifestations can be varied depending on the type of amyloid precursor in 189 question. For instance, in AL periorbital purpura is highly characteristic of CA and should prompt a tissue biopsy⁷. A comprehensive history and examination may also suggest leg/jaw claudication,
macroglossia and proteinuria⁷.

192 3.1.2 Echocardiogram:

An echocardiogram (ECHO) is very useful in illustrating the morphological changes that occur 193 over time in an amyloidotic heart and has 87% sensitivity for CA¹⁴, however the reliability may 194 vary with the practitioner's familiarity with CA on ECHO. There is an increase in bi-ventricular and 195 bi-atrial wall thickness, with no change in chamber size and dilatation respectively¹⁴. The atria 196 undergo dilatation to withstand filling pressures¹⁴. Septal infiltration and valvular thickening as well 197 as pericardial effusions are also common¹⁴. The abnormal texture of the infiltrated endo-198 199 myocardium appears as 'granular and sparkling', due to the discrepancy between the normal 200 myocytes and the shimmering amyloid protein¹⁴.

201 3.1.3 Electrocardiograph:

Low voltage QRS complexes on an ECG, in combination with the aforementioned positive ECHO findings is highly indicative of CA and is found in 50% of patients with CA. This is because CA associated ventricular hypertrophy is due to an infiltrative process and not true myocyte hypertrophy as seen in hypertrophic cardiomyopathy¹⁶. Amyloid deposits are insulative resulting in reduced QRS amplitudes⁷.

207 Combining the clinical history, ECHO findings and a discordant ECG underlines the difficulties in 208 diagnosing CA. CA is nothing short of a masquerade and mimics heart failure, hypertrophic 209 cardiomyopathy and ischaemic changes (non-Q wave infarction).

210 3.1.4 Biopsy and staining:

Endomyocardial biopsy is not the only means by which tissue can be obtained for immunocharacterisation of amyloid precursors. Extra-cardiac sites, in particular, the abdominal fat pad, are also viable possibilities^{7,16}. Aspiration of the subcutaneous fat has successfully helped diagnose CA in 85% of patients¹⁶.

The gold standard for diagnosing amyloidosis subtypes remains histological staining and immunophenotyping of tissue biopsies⁷. Stains such as methyl violet, thioflavin, and haematoxylin and eosin (H&E) can be used⁷. The most selected stain is the Congo red which under polarised light, produces an apple-green birefringence⁷. However, it should be noted that abundant collagen on aortic valves can produce a false positive Congo stain, leading to possibly an incorrect diagnosis of CA¹⁴. Gertz et al. suggest using mass spectrometry in addition to staining to better guide clinical decisions¹⁶.

3.1.5 Magnetic resonance imaging (MRI):

223 The new MRI "late gadolinium enhancement" technique has been shown to be effective in diagnosing amyloidosis⁶. This is done by identifying a characteristic pattern of increased 224 225 myocardial enhancement with other morphological findings such as increased left ventricle wall 226 thickening and abnormal myocardial and blood pool kinetics⁶. Other MRI imaging techniques such as long axis strain and myocardial contraction fraction have been shown to have great prognostic 227 value, as well as determining morphological and functional markers of disease¹⁷. However, more 228 229 evidence is needed to support the two latter techniques before they become more commonly used¹⁷. 230

231 3.2 Staging

The revised Mayo Clinic amyloidosis staging system, in addition to the New York Heart Association (NYHA) four stage system for congestive HF, can be used to determine progression and severity of AL amyloidosis^{5,8}. In Mayo Clinic staging system patient are assigned a score of 1 for each difference in FLC (difference between involved and uninvolved FLC) \geq 18mg/dL (180mg/L), cTnT \geq 0.025ng/mL, and NT-proBNP \geq 1,800pg/mL, creating stages I to IV with scores of 0 to 3 points⁸. Patients diagnosed with the Mayo Clinic staging system had rapidly decreasing survival rates with higher stages, and in a cohort treated for CA, those treated earlier on (in stage I-II of NYHA staging) had better responses to treatment¹⁸.

240 **3.3 Diagnostic epidemiological data**

As stated above, it is important to diagnose CA early on, and that clinicians are aware of the 241 cardiac and systemic signs, as well as the up-to-date diagnostic techniques for improved patient 242 243 outcomes. A 2018 epidemiological study in the United States showed an increasing proportion of the population being diagnosed with amyloidosis each year¹⁹, which suggests increasing 244 awareness of the disease amongst medical professionals. This study also noted increased 245 survival rates, which is reflected by the trends observed by a UK-based epidemiological study in 246 247 2017²⁰. This shows significant development in management of amyloidosis, and advancement in general management of complex chronic disease in elderly patients. 248

249 4. Vascular amyloidosis

The current literature has a small number of case reports on the presence of amyloid deposits in vasculature. Although some attempt is made to understand vascular amyloidosis (VA), there is no transparency regarding the frequency and extent of vascular involvement ²¹⁻²².

Amyloidosis affecting the vasculature can present as myopathy, jaw claudication and/or angina²¹. Microvascular involvement is common and often results in increased serum troponin leading to a misdiagnosis of 'non-Q wave' infarction in the absence of true coronary artery disease¹³. Myocardial flow reserve becomes impaired in VA leading to myocyte necrosis¹³. Amyloid deposits can affect the morphology of the vessel and/or the functionality. The dependent variables are frequently reported as carotid artery intimal thickness (IMT) and brachial artery flow mediated dilatation (FMD)²¹.

260 **4.1 Coronary vessels**

In a cohort study conducted by Sharma et al. AL amyloidosis was associated with a transmural deposition of amyloid whereas ATTRwt amyloidosis was found mainly in the adventitia and external media²². This implies that there is also a distinction to be made on location of deposits and not just the frequency and extent. Coronary vessels were affected in all but one in the patient group. However, it was noted that vessel lumen was significantly affected in AL amyloidosis, likely due to transmural deposit pattern²².

Smith et al. measured the frequency of vascular involvement (as well as other morphologic markers) in AL amyloidosis compared to ATTRwt amyloidosis²³. A total of 47 autopsy proven amyloidotic hearts were analysed, AL amyloidosis showed higher inclination for vasculature (90 %) whereas this figure was 4% for ATTRwt amyloidosis²³. Crotty et al found the percentages to be 88% and 26% for the AL and ATTRwt subtypes respectively²⁴.

Dorbala et al. proposed that coronary artery flow can be impeded via three different pathways: A) Deposits in the vessel wall causing stenosis of lumen (structural), B) extrinsic compression due to interstitial deposits and C) endothelial dysfunction²⁵. A comparison was made between patients with amyloidosis versus those with hypertrophic cardiomyopathy in relation to coronary perfusion²⁵. MBF (myocardial blood flow) and CRF (coronary flow reserve) were reduced in the amyloidosis group suggesting microvascular involvement²⁵.

278 **4.2 Aorta**

Amyloidosis of the aorta is more likely to be found in the ATTRwt subtype²⁶⁻²⁸. It is associated with 279 280 an increase in age and is thus a manifestation of senile amyloidosis²⁶⁻²⁸. Iwata et al. investigated 224 ATTRwt amyloidosis autopsy cases and found aortic amyloidosis to an average incidence of 281 79%²⁷. They found that the media of the aorta was affected by amyloidosis, which presented 282 283 multiple minute deposits and having no relation to atherosclerosis²⁷. ATTRwt amyloidosis in the 284 aorta has been suspected of one of the possible cause of aortic aneurysms but this claim still needs to be investigated further²⁸. There have been no comprehensive studies to suggest that 285 aortic amyloidosis is solely limited to the ATTRwt subtype, however no studies show a significant 286 occurrence of aortic involvement in AL amyloidosis²⁶⁻²⁸. 287

288 <u>5. Management and Prognosis</u>

Management of amyloidosis varies with each subtype; therefore, correct diagnosis is imperative⁷. 289 290 If incorrectly diagnosed, the prognosis can be far poorer because amyloidosis has varying causes 291 that do not respond to the same treatment⁷. One of the two main strategies used for managing 292 CA is to address cardiac symptoms and signs and improve stability⁸. Flow and conduction abnormalities are common in CA, and traditional pharmacological treatments are generally 293 advised, however they may have adverse effects that are not properly investigated in patients 294 295 presenting with CA-related HF⁸. More evidence is needed to show the potential benefit of surgical 296 interventions and device therapy. The second strategy is to address the underlying cause of cardiac symptoms by slowing the progression of amyloid deposition and is currently considered 297 the primary approach for managing CA⁸ and will therefore be the main focus of this section. 298

299 5.1 Treating the cause of CA

300 5.1.1 AL amyloidosis management and prognosis:

Patients with AL have a poor prognosis, and untreated median survival is 13 months⁷. Patients with AL and cardiac involvement have a very poor prognosis of 6-12 months after onset of congestive cardiac failure⁵. Syncope, right ventricular dilatation, left ventricular wall thickness, and elevated troponin I and T levels are all indicators of poor prognosis⁵.

Once diagnosed, AL can be treated with chemotherapeutic agents in combination with steroids⁷. 305 306 Standard treatment is cyclic oral melphalan and prednisone or dexamethasone, and the prognosis is shown to be extended to 17 months⁷. The 2015 British Committee for Standards in 307 Haematology Guideline recommends cyclophosphamide (CPA), bortezomib (BOR), and 308 dexamethasone (DEX) (together known as CyBorD or CVD), however treatment toxicity is 309 310 greater⁸. Recently, autologous peripheral blood stem-cell transplantation is suggested for far better systemic outcomes, 40% haematologic remission within a year, and prognosis extended to 311 4.6 years⁷. However, outcomes for patients with cardiac involvement remain low, with median 312 survival at 1.6 years, versus 5 months for the untreated patients⁷. The efficacy of thalidomide 313 314 combined with bortezomib has been shown and is expected to become more widely used in the future⁸. 315

Peri-transplant mortality rate has remained high for these patients, at 13%. In patients with HF 316 317 due to CA, heart transplant remains the only option alongside palliative care²⁹. Heart donations 318 are limited, and typically patients have a low chance of meeting the recipient criteria due to systemic organ involvement of amyloidosis⁷. In a small cohort of 8 heart transplant recipients, 5 319 patients had evidence of amyloid deposits 5 months after transplantation⁷. This suggests that in 320 severe CA, the progression of the disease is not halted by only replacing the damaged organ. In 321 322 more recent data, heart transplants either with or without stem cell transplant, coupled with aggressive chemotherapy to reduce the light chain replication, resulted in 100% one-year 323 survival⁵. Heart transplant remains a promising therapeutic option for cardiac amyloidosis, 324 particularly when systemic deposits are limited post-surgery with chemotherapy¹⁴. However, 5-325

326 year survival for patients undergoing heart transplant for cardiac amyloidosis was about half the
 327 survival rate for patients undergoing heart transplant for other indications¹⁴.

The most effective treatment of AL-CA remains early diagnosis and early drug treatment with a chemotherapeutic-steroidal combination.

330 5.1.2 ATTR amyloidosis management and prognosis:

The two main subtypes of ATTR (variant and wild-type), will be addressed together because of very similar pathogenesis and treatment⁸. Prognosis for cardiac-related ATTR amyloidosis (ATTR-CA) is better than for AL-CA, with median survival typically 2–6 years compared with 5-6 months⁷. Increasing amounts of evidence point to ATTR amyloidosis as a significant underlying cause of HF^{5-6,8}[5.6]. High rates of misdiagnosis lead to harmful treatments, as many traditional treatments for cardiac disease are contra-indicated or of unknown or little benefit.

Treatment for AL-CA is not indicated in ATTR-CA, therefore correct diagnosis is necessary to avoid inappropriate chemotherapy³⁰. The most effective treatment for ATTR amyloidosis remains liver transplant, as the liver produces the tetramers that misfold into amyloid proteins⁷⁻⁸. However, liver donations are not always available and some patients do not qualify for recipient criteria⁷. Furthermore, cardiac symptoms due to ATTR amyloidosis continue to progress after liver transplant, as well as retinal and cerebral deposits due to TTR production in the retinal epithelium and choroid plexus⁸.

Alternative or simultaneous (to liver transplant) treatment for ATTR amyloidosis includes drugs that inhibit liver TTR production, that stabilise TTR, and that increase excretion of TTR amyloid⁵. In 2012, Coehlo et al showed the efficacy of Tafamidis, a TTR stabiliser, for reducing all-cause mortality, cardiovascular disease hospitalisations and for improving quality of life⁸. Tafamidis has been shown to be beneficial for both ATTR-CA subtypes. Diflunisal is a non-steroidal anti349 inflammatory drug (NSAID) with tetramer-stabilising properties, but further trials are needed to 350 prove its efficacy in light of typical NSAID adverse effects⁵. Other therapeutic agents recently 351 investigated are nucleic acids, which were effective in limiting the production of TTR⁸. Patisiran, a small interfering RNA (siRNA) targeting TTR mRNA, reduced serum TTR by 80% after 18 352 months, and limited progression of cardiac signs⁸. Inotersen, an antisense oligonucleotide, was 353 also effective but had serious adverse effects⁷⁻⁸. Tafamidis and Patisiran are both recommended 354 as being potentially viable treatment options, but more trials are needed to prove their combined 355 efficacy or non-maleficence⁸. Doxycycline and (R)-1-[6-[(R)-2-carboxy-pyrrolidin-1-yl]-6-oxo-356 357 hexanoyl]pyrrolidine-2-carboxylic acid (CPHPC) have been suggested due to their TTR amyloidclearing properties but further human trials are needed to prove efficacy⁵. 358

359 **5.2 Aortic Stenosis (AS) in CA and its Prognosis:**

CA may be more prevalent in elderly men with AS and is associated with far greater mortality. 360 361 The signs of TTR CA overlap considerably with low-flow AS from other causes, and 25% of postmortem hearts of octogenarians had amyloidosis (ATTRwt) deposits⁵. This suggests a great 362 proportion of undiagnosed CA, particularly in elderly patients. In another two studies, patients with 363 severe AS and treated with aortic valve replacement (AVR) were biopsied for amyloid deposits -364 16% of which had CA in both studies, and in one study, 32% amongst the men only^{17,31}. CA-AS 365 366 had a 3-fold greater mortality rate than AS alone in patients treated with AVR (56% vs 20%)⁶. According to Java et al, AVR for other indications is not harmful in patients with 367 amyloidosis, and provides symptom relief in the mid-term³². However, prior evidence - which is 368 mostly on a handful of case studies - shows that prognosis of AVR in patients with amyloidosis is 369 370 a mixed picture ³²⁻³³. There are particularly poor outcomes for entry at the apical site and better outcomes for trans-femoral AVR³². Evidence analysed by Cicek et al. suggests that AVR make 371 no improvement to the overall mortality of patients with CA³³. Limitations to the study by Java et 372 al. is that due the small cohort of patients (n=16), with possible selection bias, and that these 373

patients have various subtypes of amyloidosis, therefore, the quality of this evidence is insufficient for a reliable recommendation for effective and sustainable treatment with AVR in patients with amyloidosis³². In another paper, AVR as well as other cardiac surgery including remodelling, are strongly advised against based on the poor prognosis observed¹⁴, probably due to the surgery being non-curative for CA. Clinicians need to be wary of misdiagnosis of more common cardiac diseases in the presence of the ambiguous cardiac amyloidosis symptoms and signs¹⁴, or "probably vastly underrecognised concomitant amyloidosis"³³.

Therefore, aortic valve replacement alone is not a suitable treatment for patients with AS caused by CA. Thorough investigation is needed to confirm and appropriately treat the underlying cause of heart disease, which is more commonly due to amyloidosis in older patients. Appropriate treatment of amyloidosis will result in better survival outcomes, as opposed to cardiac surgery alone.

386 **<u>6. Future research</u>**

There is need for evidence regarding the specific efficacy and potential adverse effects of traditional HF medication, surgery and device therapy in relation to the management of symptoms in patients with CA⁸. Additional further research also needs to be conducted in regard to developing more accurate, non-invasive diagnostic techniques.

As mentioned above, Diflunisal has potential to be used in future treatment regimes, however, randomised trials are needed to solidify its efficacy and especially weighing up its benefits compared to common NSAID adverse effects that may be associated with its use⁵. Phase 3 trials of Tafamidis have been completed further supporting its efficacy but despite this there is still a need for a randomised-control trial to further consolidate the evidence supporting it³⁴. As human trials for both Doxycycline and CPHPC are in their infancy there is still a great need for further research to be done on its use⁵. Focused research to further improve our understanding of the 398 specific mechanism and factors of misfolding is necessary in order to develop more targeted399 therapies.

400 **<u>7. Conclusion</u>**

401 Despite the rarity of amyloidosis and that it is still being underdiagnosed, the epidemiological data

402 infers that the rate of diagnosis is improving most likely due to increased awareness of the disease

403 and the development of more diagnostic techniques. The improvements in the diagnostic process

should hopefully lead to earlier and more accurate detection of the disease which have shown to

405 dramatically improve the management and prognosis of patients. Even with all these

406 improvements there is still lack of evidence in our understanding of the cause of the disease as

407 well as not enough evidence to support potential use of many of the proposed treatments. By

408 addressing this dearth of evidence regarding amyloidosis, marked further improvements can be

409 made towards better patient outcomes and their care.
