42

43

44 **Abstract**

45

46 **Objectives:** The purpose of the present study was to analyse the association between grip strength and  
47 performance of the standardised protocol of the isometric mid-thigh pull (IMTP) test.

48

49 **Methods:** 31 elite premier league footballers completed test-retest measures of **peak force (PF)** grip  
50 strength and IMTP, measures were taken 7 days apart. Post completion of the test-retest 3 maximal  
51 IMTP and bilateral grip strength measures were taken. Mean PF was calculated bilaterally for each  
52 assessment. Linear relationships were determined for test-retest and Grip Strength Test (GST) and  
53 IMTP PF output.

54

55 **Results:** Test-retest of the GST and IMTP displayed significant almost perfect correlations bilaterally  
56 ( $p \leq 0.001$ ,  $r = 0.92 - 0.94$ ,  $CI = 0.85 - 0.96$ ). Bilateral moderate-large significant correlations were  
57 also identified between grip strength and IMTP PF ( $p \leq 0.05$ ,  $r = 0.54 - 0.72$ ,  $CI = 0.30 - 0.86$ ).

58

59 **Conclusions:** GST and IMTP are reliable and repeatable measures. Findings in the present study  
60 indicate consideration must be given to the influence of grip strength on maximal IMTP PF output.  
61 Previous literature describes standardisation procedures for IMTP performance. Pre-completion of  
62 IMTP measures in elite footballers, performance practitioners should consider assessment of the  
63 athlete's grip strength despite the use of lifting straps.

64

**Abstrait**

**Objectifs** : Le but de cette étude était d’analyser l’association entre la force de préhension (ou force de grippe) et les performances sur un test standardisé de tirage isométrique mi-cuisse (TIMC).

**Méthodes** : 31 joueurs de football haut niveau de Premier League prirent part à un test-retest mesurant la force maximum (FM) de grippe et de tirage isométrique à mi-cuisse, enregistrés à 7 jours d’intervalle. À la suite du test-retest, 3 mesures maximales de TIMC et de force de grippe bilatérale furent retenues. La moyenne de FM bilatérale fut calculée pour chaque évaluation. La relation linéaire fut déterminée entre le test-retest ; et entre la force de grippe et le tirage isométrique mi-cuisse.

**Résultats** : Les test-retest de force de grippe et de TIMC bilatérale ont montré, respectivement une corrélation significative presque parfaite ( $p \leq 0.001$ ,  $r = 0.92 - 0.94$ ,  $CI = 0.85 - 0.96$ ). La FM de grippe et le TIMC bilatérale ont aussi montré une corrélation significative modérée à large ( $p \leq 0.05$ ,  $r = 0.54 - 0.72$ ,  $CI = 0.30 - 0.86$ ).

**Conclusions** : La force de grippe et le TIMC sont des mesures fiables et reproductibles. Les résultats de l’étude ici présente, indiquent que l’influence de la force de grippe sur les performances maximales de TIMC doit être considérée. La standardisation des procédures de TIMC est précédemment décrite dans la littérature. Préalable a des mesures de TIMC pour des footballeurs élites, préparateurs physiques devraient considérer l’évaluation de la force de préhension des athlètes, quand bien même ils utiliseraient des sangles.

**Mots clés** : football, conditionnement physique, risque de blessure, évaluation.

## INTRODUCTION

Injury risk factors in football are quantifiable via a battery of tests, with maximal strength commonly reported and performed by practitioners to determine a player's readiness to train or return to functional activity post injury<sup>1,2</sup>. Quantifying strength output within elite athletic populations provides contemporary debate amongst practitioners with regards to the type of test, timing of test within a training week and metrics utilised. Literature has highlighted several forms of strength measures, which include repetition max (RM), eccentric, concentric and isometric, to name a few<sup>3,4,5</sup>. The diverse nature of the equipment utilised to determine strength output also poses a predicament for sports performance practitioners, with decisions drawn on the sensitivity of the test and reliability of measures taken<sup>6</sup>. Debate surrounding the type of strength testing selected in an elite performance environment should consider the following factors: relationship to mechanisms of common injuries, transferability of the information to performance and potential detrimental effects of the test on the athlete<sup>7</sup>.

Concentric tests have been criticised in literature for not replicating muscular demand during functional performance and have limited association with the mechanisms of injury associated with common injuries in football, i.e. hamstrings<sup>8,9</sup>. Utilisation of RM testing has been documented as transferable to performance and literature has demonstrated its reliability<sup>10</sup>. The fatiguing nature of determining an individual's RM however is a concern for practitioners and utilised within a normal training week could potentially increase injury risk<sup>1</sup>. Quantifying elite athlete's eccentric strength profile is a common approach utilised within football<sup>8</sup>. This is due to its association with injury risk and functional performance<sup>9</sup>. Literature has continuously highlighted the damaging nature of eccentric muscle contractions<sup>11,12</sup>, providing sports performance practitioners with the dilemma of how to incorporate this muscle assessment when players are in competition, particularly within fixture congested periods<sup>13</sup>.

A contemporary alternative to quantify lower limb strength parameters in athletes is the isometric mid-thigh pull (IMTP)<sup>14,15</sup>. Isometric strength testing is highly reliable, has low measurement error and variability<sup>4,6</sup> and is less provocative than eccentric testing, thus reducing the risk of injury<sup>6,14,15</sup>. In addition, IMTP testing has displayed strong correlations between short explosive sprints, representing an acceleration in football to press play and speed of change of direction<sup>16</sup>. Suggesting measures of

139 IMTP link closely with performance output. However, debate exists as to whether these performance  
140 relationships exist between absolute or relative **peak force (PF)** measures<sup>17,18</sup>. Literature also highlights  
141 strong associations with dynamic strength exercises, indicating that the IMTP performance is a clear  
142 indicator of strength output<sup>19</sup>. Early research identified issues surrounding standardisation of the  
143 testing protocols within papers, but this was addressed by Comfort et al., (2019)<sup>1</sup>. Key considerations  
144 highlighted in the paper emphasised consideration of bar height, body position, grip width, foot position  
145 and consistency of these measures within each lift the athlete completes.

146

147 Literature has discussed the use of lifting straps/athletic tape to reduce the effect of grip strength as a  
148 limiting factor<sup>20,21</sup>. Although, it is noted that actual effect of grip strength when utilising the current  
149 standardised protocol suggested by Comfort et al., (2019)<sup>1</sup>, has not been analysed. Successful  
150 completion of the IMTP requires the athlete to grip the bar and push as hard as possible with the legs to  
151 generate force<sup>1</sup>. Theoretically, requiring significant grip strength to be able to perform the IMTP  
152 effectively and produce maximal force. Reliance on lifting straps to successfully perform the lift would  
153 potentially place excessive load through the wrist joint, causing discomfort to the athlete and thus the  
154 potential to reduce force application. Examination of the relationship between grip strength and IMTP  
155 performance is limited within current literature. Although handgrip strength may not be directly  
156 associated with usual characteristic assessment in footballers per se, determining whether grip strength  
157 is a factor in IMTP performance may have implications on the output generated by the athlete when  
158 performing a maximal IMTP test. Therefore, the aim of the present study is to determine the relationship  
159 between the hand grip strength and IMTP in elite players within a premier league football club.

160

## 161 **METHODS**

162

### 163 *Subjects*

164

165 Thirty-one elite U23 category 1-status academy male footballers from an English Premier League  
166 Football Club completed the present study, age 20.98±2.49 years; height 183.40±8.93 cm and weight  
167 77.65±8.38 kg. All players eligible for the study were in full training, free from injury and available  
168 for competitive selection. **Normal screening protocols completed at the club include completion of the**  
169 **IMTP test, therefore each player has been exposed to the protocols completed in the present study.**  
170 **Players were advised to refrain from caffeine or additional supplement intake up to 24 hours prior to**  
171 **data collection. This bout of testing was completed in a normal training week, mid-competitive season**  
172 **when the players had returned post a recovery day.** All participants provided written informed consent  
173 in accordance with the department and host university faculty research ethics committees, and in  
174 accordance with the Helsinki Declaration (2018).

175

176 *Design*

177

178 This was an experimental study designed to investigate the reliability of **grip strength test (GST)** and  
179 standardised IMTP test in elite footballers. Further to this, the study analysed the linear relationships  
180 between maximal grip strength on the IMTP peak force (PF) output of elite male footballers. All  
181 subjects completed all testing within the study. Prior to any testing anthropometric data of each of the  
182 athletes was taken and familiarisation trials of both the GST and standardised IMTP test were  
183 completed. Week 1 subjects were asked to complete 3 maximal seated, elbow extended grip strength  
184 measures utilising a hand-held dynamometer, followed by 3 maximal IMTP. This process was repeated  
185 on week 2. Mean scores from each of the 3 lifts were then taken for analysis from each week. Each of  
186 the familiarisation and testing sessions were separated by 7 days. Week 3 consisted of each athlete  
187 completing 3 maximal grip strength measures and 3 maximal IMTP measures. Again, mean scores of  
188 the 3 measures were taken for analysis and linear correlations were calculated for PF measures.

189

190 *Methodology*

191

192 Participants completed a familiarisation trial 7 days prior to testing to negate potential learning effects<sup>22</sup>.  
193 This included completion of 3 maximal repetitions of the hand grip dynamometer (left and right) and  
194 IMTP. Prior to any testing all participants completed the standardised dynamic warm up protocol  
195 proposed by Comfort et al., (2019)<sup>1</sup>, which consisted of 3 second repetitions of IMTP performance at  
196 50%, 75% and 90% maximal efforts, each completed 60 seconds apart. All testing was completed  
197 between 13:00 and 17:00 hrs to account for the effect of circadian rhythm and in accordance with regular  
198 competition times<sup>23</sup>. Post familiarisation trials all participants completed a test-retest to determine the  
199 reliability of measures on both the hand grip dynamometer and IMTP. Measures on both pieces of  
200 equipment were completed on two separate occasions, with 7 days between test and retest to consider  
201 learning and fatigue effects<sup>22</sup>. On completion of the test-retest data collection, participants were again  
202 given a further 7 days before completion of 3 maximal IMTP lifts and 3 maximal grip strength tests to  
203 determine correlation.

204

205 All hand grip testing was completed with the same hand grip dynamometer (Jamar ® Hydraulic Hand  
206 Dynamometer (Model J00105) (Sammons Preston, Bolingbrook, Illinois)) adhering to ASHT  
207 (American Society of Hand Therapists) clinical assessment guidelines<sup>24</sup>. The dynamometer was set at  
208 the second handle position for each participant. Each player sat in a straight-backed chair, with back  
209 supported and feet flat on the floor. The shoulder was adducted and neutrally rotated and forearm/wrist  
210 in neutral position. The elbow was extended to replicate the position it would be in when completing  
211 the IMTP, this position has previously shown excellent reliability<sup>25</sup>. The dominant and non-dominant

212 side were both subjected to 3 measures of maximal grip strength on the dynamometer, with the average  
213 of the 3 combined scores utilised for analysis.

214

215 Completion of all IMTP testing followed the standardisation protocol<sup>1</sup>. Measurements of **PF** were  
216 obtained by completing the IMTP via a force platform (ForceDecks FD4000 (ValdPerformance,  
217 Australia, 2018). Prior to completion of the IMTP correct body position for each participant was  
218 determined and repeated for each test completed. Bar height was set to replicate the 2<sup>nd</sup> pull position  
219 during the clean, adjusting to ensure that optimal knee (125-145°) and hip (140-150°) angles were set,  
220 due to body position being shown to significantly affect force generation<sup>4,14,15, 26</sup>. Angles were  
221 quantified utilising a hand-held goniometer. The goniometer was placed on the lateral femoral condyle,  
222 with upper arm following the line of the femur and lower arm tracing the line of the fibula to quantify  
223 knee angle. Hip angle was determined by placing the goniometer on the greater trochanter, with the  
224 upper arm tracing the torso and lower arm the line of the femur.

225

226 Once angles of the two joints were determined, observation of the position of the athlete was made,  
227 ensuring an upright torso with slight flexion of the knee and dorsiflexion of the ankle. Shoulder girdle  
228 was retracted and depressed, with the shoulders above or slightly behind the vertical plane of the bar.  
229 Feet were hip width apart and centred beneath the bar, with the thighs in contact with the bar.  
230 Positioning of the athlete and a final assessment was completed to ensure they were in the correct  
231 position and no tension was applied to the bar due to its negative effect on joint angle<sup>4</sup>. A record of  
232 each participant's body position ensured consistency of testing within each repeated lift. During each  
233 lift completed athletes were secured to the bar with lifting straps placed around the wrists<sup>20,21</sup>.

234

235 On the completion of each lift the athlete was provided with standardised instructions provided by the  
236 club's strength and conditioning coach. These included pushing the feet as hard as possible in to the  
237 ground; drive the feet in to the force platform not pulling the bar with the arms or rising on the toes;  
238 apply pretension to ensure correct body position and allow a pre-test force baseline (achieved by  
239 observing the force trace to ensure it was consistent with body mass); provide a countdown of 3-2-1  
240 Pull to initiate the IMTP to maximum. During the test the athlete was provided with verbal  
241 encouragement<sup>27</sup>, completing 3 successful maximal trials without any errors. Ensuring each trial was  
242 within 250N of one another<sup>20,21</sup>.

243

#### 244 *Statistical Analysis*

245

246 All participants completed 3 assessments on the hand **GST** and IMTP. Each assessment consisted of 3  
247 repetitions within each test, with maximal grip strength and IMTP PF being ascertained. Mean force  
248 for both GST and IMTP for both the left and right sides were taken for data analysis. Force data for

249 both GST and IMTP were displayed as Newtons (N) and Peak Force (PF). These values were identified  
250 for each participant and utilised for analysis.

251

252 Pearson's correlation coefficients were calculated to quantify the linear relationship between test-retest  
253 for both IMTP and GST. This was also completed to determine the linear relationship between GST  
254 and IMTP force outputs. All statistical analysis was completed using PASW Statistics Editor 25.0 for  
255 windows (SPSS Inc, Chicago, USA). Statistical significance was set at  $P \leq 0.05$ . Coefficient of  
256 correlation (r) and respective level of significance (p value) describes total variance. The following  
257 criteria quantified magnitude of the correlation  $<0.1$ , trivial;  $>0.1$  to  $0.3$ , small;  $>0.3$  to  $0.5$ , moderate;  
258  $>0.5$  to  $0.7$ , large;  $>0.7$  to  $0.9$ , very large; and  $>0.9$  to  $1.0$ , almost perfect.

259

## 260 **RESULTS**

261

262 Table 1 summarises the mean and standard deviation scores achieved for all metrics observed within  
263 the present study.

264

265 **\*\*\*Insert table 1 here\*\*\***

266

267 Test-retest of the GST displayed significant correlations for both the left ( $p \leq 0.001$ ,  $r = 0.92$ ,  $CI = 0.88$   
268  $- 0.96$ ) and right hand ( $p \leq 0.001$ ,  $r = 0.93$ ,  $CI = 0.89 - 0.97$ ). Displaying almost perfect correlations  
269 between each test, indicating excellent test-retest reliability. The same was also noted for the IMTP  
270 test-retest when utilising Comfort et al., (2019) standardisation protocol. Bilaterally IMTP PF displayed  
271 significant correlations, left ( $p \leq 0.001$ ,  $r = 0.92$ ,  $CI = 0.85 - 0.97$ ) and right ( $p \leq 0.001$ ,  $r = 0.94$ ,  $CI =$   
272  $0.91 - 0.96$ ).

273

**\*\*\* Insert Table 2 Here \*\*\***

274

**\*\*\* Insert Table 3 Here \*\*\***

275

276 Significant correlations displayed between GST, tested with the handheld dynamometer, and PF  
277 ascertained via IMTP performance on the ForceDecks (Grip (L) and IMTP (L):  $p \leq 0.05$ ,  $r = 0.72$ ,  $CI =$   
278  $0.55 - 0.86$  and Grip (R) and IMTP (R):  $p = 0.01$ ,  $r = 0.54$ ,  $CI = 0.30 - 0.77$ ). Contralateral relationships  
279 between grip strength and PF also displayed no significant correlation between Grip (L) and IMTP (R):  
280  $p > 0.05$ ,  $r = 0.22$ ,  $CI = -0.19 - 0.62$ , but significant between Grip (R) and IMTP (L):  $p \leq 0.05$ ,  $r = 0.35$ ,  
281  $CI = 0.12 - 0.60$ ). Significant correlations were also displayed between GST (L) and (R) ( $p \leq 0.001$ ,  $r$   
282  $= 0.68$ ,  $CI = 0.46 - 0.83$ ). No significant correlations were displayed between IMTP (L) and IMTP (R),  
283 ( $p > 0.05$ ,  $r = -0.02$ ,  $CI = -0.36 - 0.36$ ).

286

## 287 **DISCUSSION**

288

289 The aim of the present study was to ascertain the reliability of repeated measures of GST and IMTP  
290 within an elite football population and to investigate the relationship between grip strength and IMTP  
291 performance. PF measures within both tests were ascertained and utilised for comparison. The test-  
292 retests performed on both the GST and IMTP testing highlighted almost perfect correlations, suggesting  
293 both testing procedures were extremely reliable in this athletic population. These findings were  
294 consistent with previous literature<sup>4,6</sup>. Isometric contractions have been shown to be less damaging than  
295 other methods of muscle assessment<sup>6,14,15</sup>. Thus, making them an attractive method of assessing a  
296 player's readiness to train or injury risk, particularly in periods of competition or fixture congestion<sup>13</sup>.  
297 PF measures ascertained from the IMTP test have been associated with measures of functional  
298 performance<sup>16</sup>. Although, it is strongly debated that these PF measures are required to be relative to the  
299 subject's weight<sup>17,18</sup>. Absolute PF measures were taken within the present study, as the objective was  
300 to ascertain whether grip strength still influenced force output when completing the IMTP despite the  
301 use of the standardised protocol proposed by Comfort et al., (2019)<sup>1</sup>. **Sports performance practitioners**  
302 **should carefully consider the metrics observed when completing the IMTP test when quantifying the**  
303 **athlete's readiness to train, progression in rehabilitation or identification of injury risk.**

304

305 Main findings from the present study highlight significant moderate to large correlations between  
306 players grip strength in relation to PF and their IMTP performance (0.54 - 0.72). It is suggested that  
307 securing of the participants to the bar with lifting straps, may reduce the effect of grip strength on IMTP  
308 performance, but it does not eliminate its effect, as suggested in earlier literature<sup>20,21</sup>. Importantly,  
309 findings from this current body of work indicate that grip effect can still not be discounted despite  
310 utilisation of a standardised protocol<sup>1</sup>. Poor grip strength when performing IMTP maximally may have  
311 implications of loading through the wrist particularly when attached to the bar with lifting straps. The  
312 straps and load applied when performing the test may cause a distraction of the wrist, resulting in  
313 discomfort to the athlete and thus reducing the amount of force applied. The effects of this could be  
314 catastrophic in youth athletes with an immature skeleton<sup>28</sup>. It must also be considered that athletes may  
315 place less emphasis on gripping the bar due to the attachment of lifting straps. Either scenario could  
316 potentially result in reduced/poor performance or injury risk.

317

318 Practitioners must be prudent to advise that despite the use of lifting straps athletes must apply maximal  
319 grip to the bar when performing. This approach should be considered in any standardisation protocol  
320 associated with the IMTP. Previous literature<sup>20,21</sup> cited by Comfort et al., (2019)<sup>1</sup> identified the use of  
321 lifting straps, taping or a combination of both. Both papers described that the utilisation of these  
322 methods ensured that grip strength was not a limiting factor in the IMTP protocol. It is important to

323 note that although these papers identified interclass correlation coefficients (ICC) scores for the  
324 described methods completed, they did not identify grip strength performance of the athletes.  
325 Comparisons were made between varying metrics associated with IMTP and a dynamic lift. Therefore,  
326 not allowing the assumption that grip strength was no longer a limiting factor. The present study  
327 directly identifies relationships between grip strength and IMTP performance. Further research in this  
328 area should consider ICC values of athletes performing IMTP with and without wrist support, but also  
329 compare outputs in relation to wrist support method utilised in the lift.

330

331 Recent studies indicate several positive reasons for utilising the IMTP test as a method of quantification  
332 to inform injury risk, readiness to train or play or a progression marker in rehabilitation<sup>29,30</sup>. The  
333 findings of the present study clearly support these earlier conclusions. Emphasis is placed on legs  
334 pushing through the floor during performance of the IMTP to exert maximum output. Although the  
335 present study analyses the effect of grip strength it is important to appreciate that performance of the  
336 IMTP requires stabilisation of the hips, as well as maintaining a good posture representative of the  
337 second pull position. Any failure to maintain this throughout performance of the IMTP may result in  
338 inaccurate outputs being produced. If the grip strength of the athlete is not adequate the athlete may  
339 create pull from other areas of the body, meaning an adjustment of the position described in the methods  
340 of the current and previous papers<sup>1,4</sup>. It is important to emphasise to the athlete or practitioners the  
341 effect inadequate grip application may have on performance. Thus, highlighting that pre performance  
342 of this test practitioners may consider performance of a GST.

343

#### 344 *Limitations:*

345

346 The present study identifies relationships between grip strength and IMTP performance. Limitations  
347 exist within the present body of work, most notably failure to consider other metrics exhibited during  
348 the IMTP test. Future work in this area could consider other performance metrics exhibited in the IMTP  
349 test like rate of force development (RFD), another metric like PF that has been strongly associated  
350 within literature with functional performance<sup>1</sup>. Positioning of the athletes during testing was  
351 standardised in relation to protocols described in previous work, but the effect of poor positioning was  
352 not quantified<sup>1</sup>. Further research should consider the effect poor grip strength may have on the athletes  
353 positioning when performing the IMTP test. Consideration must also be given to other limiting factors  
354 associated with the performance of the IMTP, which may include reduced dorsiflexion of the ankle or  
355 poor shoulder and shoulder girdle function. Sports performance practitioners need to consider the  
356 importance of these factors and appropriately screen the athlete to ensure optimal performance can be  
357 achieved when completing the IMTP test.

358

#### 359 **PRACTICAL APPLICATIONS**

360  
361  
362  
363  
364  
365  
366  
367

- Consideration must be given to the effect of grip strength on IMTP performance when utilised as a test to quantify maximum PF in elite footballers.
- Although grip strength has implications on maximum PF output, the IMTP test still represents a reliable and repeatable test for quantifying PF output in elite footballers.
- Careful consideration should be given to assessing the grip strength of the athlete pre completion of the standardised protocol for IMTP test.

## 368 **APPLICATIONS PRATIQUES**

369  
370  
371  
372  
373  
374  
375

- L'effet de la force de grippe sur les performances de TIMC doit être considéré dans un test de force maximal pour des joueurs élités de football.
- Bien que la force de grippe soit impliquée dans la force maximal produite, le TIMC reste un test fiable et reproductible pour la quantifier la force maximale de joueurs élités de football.
- L'évaluation de la force de grippe des athlètes préalablement a un test standardise de TIMC devrait être considérée avec attention.

376  
377  
378

## 379 **CONCLUSIONS**

380  
381  
382  
383  
384  
385  
386  
387

The findings of the present study suggest that grip strength has an influence on IMTP test performance. The importance of a standardised protocol has previously been identified and should continually be utilised within IMTP testing within elite sports performance environments. Although it is important for practitioners to consider the assessment of an athlete's grip strength pre a maximum PF test. Further research should consider the utilisation of quantifying maximum PF output with the IMTP. Thought should be given to analysing grip strength and other quantifiable measures of lower limb PF.

## 388 **CONCLUSIONS**

389  
390  
391  
392  
393

Les résultats de l'étude ici présente suggèrent que la force de grippe a une influence sur les performances de test de TIMC. L'importance d'un protocole standardise a déjà été identifié précédemment, et devrait continuer à être utiliser pour le test TIMC dans le contexte de la performance sportive de haut niveau. Il est toutefois important pour les préparateurs physiques de considérer l'évaluation de la force de grippe

394 des athlètes avant un test maximal de TIMC. Davantage d'études devraient considérer l'utilisation de  
395 quantifier les mesures maximales de force de TIMC. Une attention particulière devrait être donnée à  
396 l'analyse de la force de grippe et autres mesures quantifiables de la force maximale des membres  
397 inférieurs.
