# What else lies behind the Credit Rationing? Exploring the issue of Employment.

---

## Abstract

The relationship between credit rationing and employment attracted scholars' attention in the aftermath of the Great Recession. Researchers, using a plethora of measurements and models, have examined the effect of credit rationing and its different manifestations and effects on employment, even though some issues have remained unexplored to date. This paper reviews the literature extensively by analysing recent work and providing a guide for models, datasets and research findings within the context of capital market imperfections. We further break down the literature into closer in nature categories for reader's convenience and comprehension. Finally, we address gaps in the existing literature and propose government policies that can tone down the potential effect of credit rationing on employment.

**Keywords:** Information Asymmetry, Small Business Lending, Credit Rationing, Employment, Discouragement.

## **1. Introduction**

Most of the studies, since the mid-1960s, have isolated firm real decisions from financial factors with Modigliani and Miller (1958) characteristically demonstrating the so-called Irrelevance Theorem. The main conclusion was that a firm's financial structure will not affect its market value within a perfect capital markets context suggesting that a firm's financial status is irrelevant for real investment decisions. The Modigliani and Miller theorem was attractive because it allows researchers to ignore the complications posed by financial considerations. In particular, the developers of the neoclassical theory of investment, Jorgenson (1963) and Hall and Jorgenson (1967), advocate that a firm's optimization problem could be solved without reference to financial factors like internal cash reserves, debt utilization or dividend payments, qualifying the user cost of capital as the sole determinant of investment. Consequently, internal and external finance are viewed as substitutes; firms use external finance to smooth investment when internal finance is scarce. Empirical research has, however, usually produced results that are at odds with the Modigliani-Miller (1958) propositions on financial irrelevance.

In this vein, over the past few decades, several studies have emerged deviating from the traditional business fixed investment models by integrating the influence of financing constraints into the determination of a firm's investment decisions. Such a deviation from the paradigm of perfect capital markets is characterised by *ex-ante* and *ex post* asymmetries of information between lenders and borrowers, leading to an equilibrium outcome where the assumed perfect substitutability between internal and external sources of finance breaks down (Greenwald, *et al.* 1984; Mayers and Majluf, 1984). Consequently, a cost differential, known as the External Finance Premium, exists between external and internal funds, with the former being more costly than the latter (Townsend, 1979; Greenwald, *et al.* 1984; Myers and Majluf, 1984; Bernanke and Gertler, 1990; Gertler, 1992; Kiyotaki and Moore, 1997). In this context, numerous studies have investigated the properties of such equilibrium in situations where lenders (principals) cannot costlessly obtain information about the opportunities, characteristics or actions of borrowers (agents) (Townsend, 1979; Stiglitz and Weiss, 1981; Greenwald, *et al.* 1984; Myers and Majluf, 1984; Bernanke and

1  
2  
3 Gertler, 1990; Gertler, 1992; Kiyotaki and Moore, 1997). Hence, asymmetric information  
4 by its own **exacerbate** financing constraints.

7 Asymmetric information in debt financing may increase the cost of new debt or  
8 even restrict firms from borrowing due to credit rationing (Stiglitz and Weiss, 1981;  
9 Greenwald, *et. al.* 1984). **The term credit rationing is employed to describe situations in**  
10 **which either** a) among loan applicants who appear to be identical, some receive a loan, and  
11 others do not even if they are willing to pay higher interest rate, or b) there are identifiable  
12 groups of individuals in the population who, with given loan supply of credit, are unable  
13 to get a loan at any interest rate, even though with a larger supply of credit, they would. In  
14 this framework, the emphasis on capital market imperfections may have an important  
15 negative effect on real economic variables such as investment (e.g. Tybout, 1983; Oliner  
16 and Rudebusch, 1992; Carpenter and Rondi, 2000; Drakos and Kallandranis, 2005a,b;  
17 Campello et al., 2010; Gerlach et al., 2015; Kallandranis, 2019; Kallandranis et.al., 2020  
18 etc.), real growth rates (e.g. Blinder & Stiglitz, 1983; Bencivenga & Smith, 1993), exports  
19 (e.g. Arkolakis et al., 2010; Cheng et al., 2021; Pietrovito & Pozzolo, 2021), productivity  
20 (e.g. Yu & Fu, 2021), inflation (Gao et al., 2012; Akinkoye et al., 2015), R&D and  
21 innovation activities (Santos & Cincera, 2022 ; Vlassas et al., 2023) and employment (e.g.  
22 Benmelech et al., 2011; Chodorow, 2014; Duygan et al., 2015).

34  
35  
36 It is rather visible from the above analysis that the role of capital in a context of  
37 financial frictions has been put at the centre stage in the literature of real firm investment  
38 decisions. Indeed, capital is acknowledged as a main factor in firms', and not only, growth  
39 output. However, the role of financing constraints in the firm's investment decisions **has**  
40 **left the equally significant employment factor almost neglected. In this vein, such models**  
41 **can reveal interesting interlinkages of the credit market with the labour market,**  
42 **demonstrating how frictions in financial markets can magnify volatility not only at capital**  
43 **level but at employment level too. Such a relationship can have important effects on the**  
44 **real economic activity, however only a handful of relevant studies have explored this issue**  
45 (e.g., Campello et al., 2010; Benmelech et al., 2011; Ferrando & Muelier, 2015; Gerlach et  
46 al., 2015; Gomez, 2019).

Indeed, if a firm formulates its employment decisions within a Modigliani-Miller (1958) world, such an economy would be characterized by a dichotomy between the real and financial decisions of firms and full reversibility of production decisions (e.g. Drakos and Kallandranis, 2006). This ideal environment guarantees that in the occurrence of a stochastic shock, labor demand would respond fully and immediately to its long-run state variables. On the contrary, imperfections in the capital markets, often stemming from information asymmetry, tend to result in suboptimal decisions for firms classified as financially distressed. To the extent that these imperfections cause the breakdown of the MM theorem then the otherwise irrelevant, financial aspects of the firm will be correlated with employment decisions. As a result, the short-run dynamics of labor demand will be sensitive to variations in the financial profile of employment decision-making agents. In particular, employment decisions when the firms are in financial distress can be affected through the higher cost of external funds (Sharpe, 1994). Hence, an additional feature of the consequences of capital market imperfections and ultimately credit rationing is the possible effect of frictions on labor demand.

Albeit the relationship of credit rationing and investment has had a significant focus within the credit rationing literature, surprisingly not a vast number of studies have been conducted on the relationship of credit rationing and employment. From a macroeconomic scope of analysis, growth of capital markets can create what is called by Pagano & Pica (2012) as “jobless growth”: firms may invest in technologies that are more capital-intensive, resulting in an increase on productivity but not employment. Consequently, a positive relationship between enhanced financial accessibility and growth may not necessarily translate into a positive link between finance and employment. Even if this positive link is true, it does not render into an increase in employment across all industries and firms. Indeed, as financial intermediaries become increasingly selective and cautious on their resource allocation this leads towards firm closures, layoffs and general firm restructuring if firms’ outlook is not considered positive. However, this is not a definite conclusion as more developed financial markets and intermediaries can also fund firms with negative outlooks bearing liquidity challenges to improve their prospects and stabilize their financial profile. Albeit these two countering effects are linked, the positive effect of the growth of financial markets receives significantly more public debate over the negative one.

1  
2  
3 In the scope of within-firm analysis, theoretically, credit rationing should affect  
4 firm employment decisions for a number of reasons. First, if a mismatch on labour costs  
5 and a firm's cash flow exists, then firms will have to finance such costs from the production  
6 process (e.g. Greenwald & Stiglitz, 1988) resulting in employment fall when the ability to  
7 finance capital is not optimal. Second, there is a possibility especially for larger firms that  
8 labour is not solely a variable cost in production (e.g., Oi, 1962; Hamermesh and Pfann,  
9 1996) but has also a fixed or quasi-fixed cost component through procedures like hiring  
10 and training of employees. Third, credit rationing might affect employment indirectly in a  
11 firm via its impact on investment (Benmelech, 2011). Indeed, capital market frictions  
12 hinder investment as firms are constrained by the available internal funds of firms which  
13 due to the complementary nature between labour and capital, employment is adjusted to  
14 account for the decline in capital.

15  
16 Within the concept of the previously reported factors, the conventional issue of  
17 credit rationing becomes even more pertinent for small and medium sized enterprises  
18 (SMEs henceafter) as, due to their size, they experience challenges related to  
19 informational opacity and lack of substantial collateral, making them more susceptible to  
20 credit rationing problems (e.g., Stiglitz & Weiss, 1981; Jaffee & Stiglitz, 1990; Liberti &  
21 Petersen, 2019, Kallandranis et.al., 2023 etc.). The decline in SME's lending has received  
22 much attention from researchers and policymakers as a consequence of its potential link to  
23 important economic measurements such as investment and unemployment rates. It is well  
24 known that the main challenge that SMEs have to encounter in their environment is the  
25 lack of demand for their goods and services (Gerlach et al., 2015), but changes in bank  
26 credit and other supply-side factors are also of significant importance to SME's  
27 performance. Disruptions in the flow of bank credit may have notable real effects on the  
28 labour market (Duygan et al., 2015) and the functioning of SMEs, as they lack viable  
29 alternatives to bank credit.

30  
31 In this respect, policymakers need to comprehend which factors support or hinder  
32 SMEs performance and develop a plan that will help them flourish in their respective  
33 business environments (Greenstone et al., 2020), as they contribute more than 50% of  
34 global employment according to World Bank. Such a plan is critical to a sustained  
35

2  
3 employment recovery. In this context, the issue of credit rationing is intensified for SMEs  
4 in low and middle-income economies (LMIEs) in comparison to advanced economies  
5 (Beck et al., 2008; Ayyagari et al., 2012) due to problems such as underdeveloped credit  
6 markets and less competitive banking systems that makes them less capable in dealing with  
7 informational asymmetries (Gutierrez et al., 2021). Thus, SMEs in LMIEs face higher loan  
8 rejection rates and higher interest rates which may contribute, as mentioned above, to a  
9 mismatch on labour costs and a firm's cash flow. Firms have to finance such costs from  
10 the production process (e.g. Greenwald & Stiglitz, 1988) resulting in employment decline.

11  
12

14  
15  
16  
17  
18 This paper is prompted by the scarcity of research investigating credit rationing's impact  
19 on the real firms' decisions, despite its substantial significance for SMEs and global  
20 economies. It focuses on creating an extensive literature review based merely on the  
21 relationship of credit rationing and employment and it contributes to the existing literature  
22 in a number of ways. The latter has been neglected in the literature relative to the traditional  
23 liquidity approach of capital market imperfections. We contribute to the existing literature,  
24 since according to our knowledge, there are not enough recorded papers that provide an  
25 analytical review of the relation between credit rationing and employment. Second, we  
26 attempt to create a road map that will gather the different approaches on examining this  
27 relationship and categorise them accordingly. Third, we analyse the specifications of each  
28 category and at the end provide pointers to guide future research.

36  
37  
38 The paper is organized as follows. In Section 2.1, we outline the fundamental  
39 framework of our categorization and elaborate on the methodology employed in  
40 conducting our research. In Sections 2.2-2.4, we classify the existing literature into  
41 categories based on the independent variables that the models used. Finally, in Section 3,  
42 we refer to the results of our review, the gaps of the current literature, and possible ways  
43 to counter them in future research. For the convenience of the reader, tables are provided  
44 including a list of the most relevant papers throughout the analysis.

## 45 46 47 48 49 50 **2.1. Empirical Literature Classification**

51  
52  
53 Before delving into the analysis of the relationship of credit rationing and  
54 employment, it is important to understand and account for measurements that may change  
55  
56  
57  
58  
59  
60

1  
2  
3 the statistical importance of this relationship. Researchers, in order to produce robust  
4 results, have incorporated a wide range of control variables to ensure their models are free  
5 from biased and inaccurate results.  
6  
7

8  
9 In order to compensate for the absence of significant information about firms past  
10 borrowing history, the use of certain variables should be treated very cautiously. The  
11 relevant literature makes use of qualitative data that can serve as proxy variables to examine  
12 risk characteristics on both the supply and demand sides. This analysis takes into account  
13 variances in the investment opportunity set, as described by Hubbard (1998). The  
14 correlation between this opportunity set and suitable proxies that capture elements of  
15 information flows and transparency is significant, which can certainly impact the cost of  
16 capital. In this context, the regressor most frequently employed in models related to credit  
17 rationing and employment is that of size (Campello et al., 2010; Chodorow, 2014; Duygan  
18 et al., 2015; Gerlach et al., 2015; Popov & Rocholl, 2015; Giroud & Mueller, 2015;  
19 Bentolila et al., 2018; Berg, 2018; Siemer, 2019; Gomez, 2019; Farinha et al., 2021). Large  
20 firms possess greater resources to withstand economic shocks and are less susceptible to  
21 informational asymmetries compared to smaller counterparts. Furthermore, due to their  
22 relatively bigger size, it is easier to adjust their employment status accordingly, when the  
23 economic circumstances change substantially. However, the way size is implemented  
24 within empirical model changes based on data availability of firms as well as researcher's  
25 preference. Generally, researchers prefer to distinguish between two (2) different  
26 categories of size; large and small firms. The criteria used to make this distinction are  
27 usually the number of employees within a firm, using most of the times a benchmark of  
28 less than 50 or 250 employees to define a firm as small, and turnover, where the benchmark  
29 value varies depending on the country and industry of the data.  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45

46 Additionally, firm age is a common control variable utilized in such models  
47 (Chodorow, 2014; Ferrando & Mulier, 2015; Gerlach et al., 2015, Bentolila et al., 2018;  
48 Berg, 2018 ; Siemer, 2019; Gomez, 2019). Specifically, longevity can suggest an inherent  
49 capacity of the company to survive, which would signal its quality and hence decrease the  
50 presence of asymmetric information, and consequently enhance opportunities for bank  
51 financing. Regarding its correlation with employment, during the initial stages of a firm's  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 existence, employment growth is heavily influenced by the increase in production of goods  
4 or services. Therefore, it is logical to assume that the longer a firm has been operating, the  
5 higher the chance to employ a greater amount of personnel.  
6  
7

8  
9 A group of control variables that **recurrently** appears in these empirical models are  
10 metrics that reflect financial stability of a firm. Profitability (Kleeman & Wiegand, 2013;  
11 Gerlach et al., 2015; Popov & Rocholl, 2015; Gomez, 2019; Farinha et al., 2021), turnover  
12 (Caggese & Cunat, 2008; Gerlach et al., 2015; Berg, 2018; Gomez, 2019), cash flow  
13 (Benmelech et al., 2011; Popov & Rocholl, 2015; Cao & Leung, 2020) and liquidity  
14 (Benmelech et al., 2011, Popov & Rocholl, 2015; Cao & Leung, 2020) and liquidity  
15 (Kleeman & Wiegand, 2013, Berg, 2018) are the most **commonly employed**. They are used  
16 either as absolute or relative values, primarily as ratios with assets. Originally a high value  
17 of such metrics means a probable greater employment growth for a firm. Similarly to  
18 financial stability measurements, debt related measurements such as bank dependence  
19 (bank debt over total debts), debt to assets ratio (Gomez, 2019; Cao & Leung, 2020; Farinha  
20 et al., 2021) and lagged debt levels (Gerlach et al., 2015) examine the relative financial  
21 healthiness of a firm. Finally, **beyond** firm specific variables, there are also country,  
22 industry and time characteristics that **could impact** this relationship between credit  
23 rationing and employment. To account for these effects, researchers may use fixed effects  
24 for different countries, times and industries, **adjusting based** on the variability of the  
25 datasets.

34  
35  
36

37 Under this theoretical and empirical context, we have classified the empirical  
38 literature into three main categories depending on the focus of the relationship of  
39 employment and credit rationing as well as credit supply shocks. In particular, we focus on  
40 1) a set of variables measuring employment and how credit rationing affects it based on  
41 survey (Dromel et al., 2010; Benmelech et al., 2011; Pagano & Pica, 2012; Berg, 2018;  
42 Siemer, 2019) and non-survey data (Caggese & Cunat, 2008; Campello et al., 2010;  
43 Ferrando & Mulier, 2015; Gerlach et al., 2015; Gomez, 2019; Cao & Leung, 2020), 2) **the**  
44 **impact of credit supply shocks on the growth of employment at the macroeconomic level**  
45 (Benmelech et al., 2011; Giroud & Mueller, 2015; Hochfeller et al., 2015; Greenstone et  
46 al., 2020; Gutierrez et al., 2021) and on bank to firm relationship level (Chodorow, 2014;  
47 Popov & Rocholl, 2015; Acharya et al., 2018; Bentolila et al., 2018; Farinha et al., 2021)  
48

55  
56  
57  
58  
59  
60

1  
2  
3 and 3) the significance of balance sheet measurement in influencing employment growth  
4 (Hernando & Carrascal, 2008; Spaliara, 2009; Benmelech et al., 2011; Duygan et al., 2015;  
5 Giroud & Mueller, 2015; Berton et al., 2018). The most prominent studies across the  
6 aforementioned categories are presented in Tables 1-5, giving the reader a comprehensive  
7 classification and analysis of their content. We also provide a tree diagram in order to depict  
8 the three main aspects mentioned above.  
9

10  
11  
12  
13  
14 **(Insert Diagram 1 here)**  
15

16 The relevant literature utilizes predominantly balance sheet measurements over  
17 survey data to analyse the relation of credit rationing and employment. Despite the  
18 availability of various databases and datasets, there is a preference in the usage of  
19 Compustat (Benmelech et al., 2011; Duygan et al., 2015; Giroud & Mueller, 2015; Siemer,  
20 2019) and other global databases like Dealscan and Bankscope. Moreover, since the  
21 employment variable is mostly measured through percentage changes over time,  
22 implementation of least squares, two-stage least squares and the generalized method of  
23 moments models are the most commonly used within the literature over other binary  
24 models like probit and logit. In order to measure pre and post event effects, researchers  
25 also commonly use methods like the regression discontinuity design, propensity score  
26 matching and difference-in-difference models. Regarding the periods under scrutiny, the  
27 selected studies encompass a time span of 15 years (2008-2023) and include a wide variety  
28 of countries and samples, while the data availability on years range from 1970-2017,  
29 covering 47 years in total. The variety of different countries and time spans for relevant  
30 research allows us to examine whether the relationship of credit rationing, and employment  
31 holds true under distinct economic cycles.  
32  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42  
43

44 Regarding the adopted methodology, several steps were implemented in order to  
45 sort out the relevant literature. First, we set out the basic criteria for our research, which  
46 were related with how all different forms of credit rationing affect the employment of a  
47 firm, focusing on SMEs and banks. Second, we chose the Google Scholar and  
48 ResearchGate search engines, to browse and read through relative papers along with  
49 academic publishing companies specializing in related scientific fields. Our search was  
50 conducted in English and all the papers used in our review were published within the last  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 15 years (2008-2023), since the modern empirical model measurements of this relationship  
4 started after the Great Recession. The keywords we used for our research were:  
5 “employment and credit rationing”, “employment and financial constraints” and  
6 “employment and credit supply shocks”. We also conducted the same browsing methods  
7 followed by the two keywords “in SMEs” and “banks”, to monitor better relevant studies.  
8  
9 Third, we initialised the basic screening procedure, by reading abstracts of relevant papers  
10 and delving into details of those closely related to the relationship of credit rationing and  
11 employment. After assessing the relevance of these papers to our research interest, their  
12 robustness in terms of econometric results and the journals under which they were  
13 published, we ended up with the studies presented in the following Sections and Tables. In  
14 the fourth and final step, we classified those papers into 5 separate categories, based on the  
15 different ways credit rationing, financial constraints and credit supply shock were applied  
16 on econometric models. We included only research that was relevant with our study and  
17 excluded other independent and dependent variables for reader’s convenience, as they are  
18 not within the concept of the relationship we want to examine.

## 32 **2.2. Credit Rationing and Employment on Survey & Non-Survey Data**

33  
34  
35 The first category of credit rationing and employment we constructed is related to  
36 the direct analysis of their correlation, dividing them between research conducted on  
37 survey and non-survey data. Ever since the analysis of survey data emerged, a debate has arisen  
38 over its usefulness relative to other forms of data analysis like balance sheet measurements  
39 and databases. Specifically, survey data allow researchers to collect specific information  
40 tailored to the variable of their interest, since questions can be designed to directly address  
41 them. Nevertheless, survey responses could be prone to bias. This bias may arise either  
42 from the respondents who might be reluctant to disclose personal information about their  
43 enterprise or from the researcher who could have formulated questions in a way that leans  
44 towards a specific response. That being mentioned, it is unquestionable that both forms of  
45 data analysis can provide different types of results that can be helpful when analysing the  
46 relationship of credit rationing and employment.

A similar point in both forms of analysis is the use of the employment variable. As a variable to measure, employment is quite straightforward. Researchers mostly prefer to compute the percentage change of employment over time (Campello et al., 2010; Benmelech et al., 2011; Chodorow, 2014; Giroud & Mueller, 2015; Hochfeller et al., 2015; Bentolila et al., 2018; Berg et al., 2018; Berton et al., 2018; Siemer, 2019; Gutierrez et al., 2021) and analyse how their primary finance variable influences that change while controlling for other key factors. However, it should be noted that there are unique approaches to its computation too. For example, in this first subcategory of papers summarized in Table 1, Ferrando and Muelier (2015) compute future employment growth a period ahead and not earlier. Gomez (2019) measures employment fluctuations relative to the prior year of the firm and does not account for the level of change. Gerlach et al. (2015) use the absolute value of the number of employees within a firm when researching how its financial measurements affect it. Caggese & Cunat (2008) delve deeper into the analysis of employment and research the impact of fixed time workers over permanent workers ratio on changes in credit constraints.

Since the dependent variable of all analysed models (employment) is similar in nature, we proceed with categorisation based on the financial measurements utilised. In the papers outlined in Table 1 (survey data analysis), three different types of independent variables can be spotted: a) credit constrained variables (Caggese & Cunat, 2008; Gerlach et al., 2015; Gomez 2019), b) discouraged borrowers variables (Ferrando & Muelier, 2015; Gerlach et al., 2015) and c) financial constraints indicators (Caggese & Cunat, 2008; Campello et al., 2010; Cao & Leung, 2020). The existing literature on credit rationing (Ferrando & Muelier, 2015; Gerlach et al., 2015; Ferrando et al., 2017; Gomez, 2019) brand a firm as credit constrained either when a) a firm's loan was rejected by a bank, b) a firm only received a limited amount of the loan proposed (70-75% of the amount requested, based on the categorisation of the survey) and c) a firm rejected a loan proposal by the lender due to high interest rate costs. In this segment of the literature, Caggese & Cunat (2008) discovered that firms facing more pronounced credit constraints increase substantially the utilization of fixed-term workers over permanent workers. All in all, they demonstrate that the flexibility of fixed-term workers is crucial for firms encountering problems in credit availability, leading to significant increase in total employment volatility

1  
2  
3 in an industry. On the other hand, Gomez (2019) doesn't differentiate between discouraged  
4 and credit rationed firms but takes into consideration not only bank financing but also other  
5 forms of financing like credit lines, bank overdraft and trade credit. Gomez (2019) reported  
6 that credit constraints do not have a significant effect on employment growth.  
7  
8  
9

10  
11 **(Insert Table 1 here)**  
12

13 According to Jappelli (1990), firms are defined as discouraged borrowers when they do  
14 not apply for a loan due to fear of possible rejection. In a relative short note, we need to  
15 highlight that this strand of literature, has received an overly low attention and only recent  
16 studies have explored the discouraged borrowers in credit dynamics and documented its  
17 importance in the credit markets (e.g., Levenson & Willard 2000; Chakravarty & Yilmazer,  
18 2009; Popov & Udell, 2010; Freel *et al.*, 2012; Anastasiou *et al.* 2022; Kallandranis *et al.*,  
19 2023). In this context, discouraged firms are prevalent in banking systems that: a) credit  
20 supply is limited, b) banks can't screen appropriately the firms applying and c) the  
21 application cost for firms is positive (Kon & Sotrey, 2003) and significant relative to its  
22 estimated chances of the loan being accepted. Kon & Storey (2003) formulated a model  
23 demonstrating that firms become discouraged when the total effective costs of borrowing  
24 exceed the expected profits of investing from the utilisation of the bank loan. Within the  
25 context of the relationship of employment and credit rationing, Ferrando & Muelier (2015)  
26 developed a model that accounts for the inherent endogeneity issues of discouragement,  
27 since discouraged borrowers typically encounter worse growth opportunities compared to  
28 the average firm. In order to counter that problem, they used an instrument that measures  
29 firm level financial constraints where firms are asked to report the most pressing hurdle  
30 they face. In their results, they found that employment growth is 2.7% lower for  
31 discouraged borrowers relative to firms that applied for a loan in the two years following  
32 their discouragement status. Likewise, Gerlach *et al.* (2015) found a significant negative  
33 effect of credit constraints and discouragement on employment of SMEs. When they split  
34 the sample between discouraged borrowers and credit rationed firms, they report that the  
35 main driving factor for that negative effect are discouraged borrowers.  
36

53 Other financial constraints indicators reported in surveys can be observed in the  
54 research conducted by Campello *et al.* (2010) and Caggese & Cunat (2008). Campello *et*  
55  
56  
57  
58  
59  
60

1  
2  
3 al. (2010) employ a financial constraints indicator based on firms reporting whether they  
4 are affected by financial problems (3 subcategories – not affected, somewhat affected, very  
5 affected). They found that there is a 6% employment reduction on firms that report high  
6 financial constraints. Cao & Leung (2020) assess the likelihood of firms facing financial  
7 constraints by assigning scores based on their reported financial status. After pooling the  
8 results, they divided firms into three subcategories depending on whether firms requested  
9 external financing even though they needed it (most likely constrained), requesting and  
10 successfully acquiring their loan (unlikely to be constrained) and requesting but getting  
11 lower amount of the loan than expected (likely constrained). Finally, Caggese and Cunat  
12 (2008) used a financial constraint indicator labelled on the survey as ‘willing to pay higher  
13 interest rate than the market’s’ in order to reach the aforementioned results.  
14  
15  
16  
17  
18  
19  
20  
21  
22

23 The second part of this category we have constructed is that of credit rationing and  
24 employment on non-survey data (see Table 2 for details). We have further divided this  
25 category into two different segments: a) firm level analysis (Benmelech et al., 2011; Berg,  
26 2018) and b) non-firm level analysis (Dromel et al., 2010; Pagano & Pica 2012; Siemer,  
27 2019). Under firm level analysis, Benmelech et al. (2011) researched how long-term debt  
28 that matures the coming year for a firm and represents more than 5% of the firm’s assets  
29 affect its employment status. Since the debt was issued two, three or four years prior to  
30 their data, they posit that the variation of the amount of long-term debt maturing in any  
31 given year is exogenous to firm outcomes of the years covered by the data. In their results,  
32 they discover a significant and negative correlation between the maturing long-term debts  
33 and changes in employment. Berg (2018), in a research paper focusing especially on SMEs,  
34 developed a bank evaluation model for firms assigning them a rating of 1-11 based on hard  
35 firm information. Loan applications with a rating surpassing the bank’s cut-off value (1-7)  
36 were accepted, while loan applications with a rating worse than that value was subjected  
37 to further review (7-9), leading to a drop, in loan acceptance rate. Firms whose value was  
38 on the 10-12 threshold were rejected. Berg’s model showed that the economic effects for  
39 SMEs are significant, with a reduction of 1% in credit supply translating into a drop in  
40 employment of almost 1%.

56  
57  
58  
59  
60

Under non-firm level analysis, Dromel et al. (2010) focus their research on country level, Pagano & Pica (2012) on country and sector level, while Siemer (2019) on sector level. In detail, Dromel et al. (2010) addressed the literature gap on how credit frictions influence the transitional dynamics of unemployment. The underlying idea of their model is that unemployment (the dependent variable of the model) may rise by frictions in the credit markets. This assertion is corroborated by the outcomes of their model, demonstrating a negative association with credit rationing (measured as the share of private credit by deposit money banks divided by the country's GDP) and a country's unemployment rate, mostly through its lagged value. Pagano and Pica's (2012) principal theoretical basis for their model is based on the hypothesis that financial growth on employment should differ across industries, depending on their need for external finance. For the creation of their model, they divide countries into high financially developed countries and low financially developed countries based on the average ratio of stock market capitalization to GDP. They report that the effect of finance on employment is positive and statistically significant in developing countries but not in developed ones while the financially dependent sectors experience lower employment growth. In conclusion, Siemer (2019) focuses primarily on the employment growth of young versus old firms by using an indicator that measures external financial dependence, utilising info on size, age and industry of firm. Using a difference-in-differences estimator, it is highlighted that, during the recession, employment growth diminishes by 8% in small firms compared to large firms. This differential effect is predominantly due to the impact of financial constraints on young firms.

### **2.3. Credit Supply & Employment**

The second category of credit rationing and employment is subject to credit supply shocks that may hamper bank financing as they become more selective in their lending practices. A reduction in credit availability may lead to a decline in business investment and profits, forcing firms to cut back on capital expenditures. The decrease in investment could typically impact employment growth within firms. This issue has an especially significant impact on SMEs that face higher asymmetric information and lower

1  
2  
3 creditworthiness relative to bigger firms. As a result, credit supply shocks may have a more  
4 severe impact on SMEs, where credit rationing can result in extended employee layoffs  
5 and hiring freezes.  
6  
7

8  
9 Researchers have investigated thoroughly the effect of credit supply shocks on  
10 employment (Benmelech et al., 2011; Chodorow, 2014; Giroud & Mueller, 2015;  
11 Hochfeller et al., 2015; Popov & Rocholl, 2015; Acharya et al., 2018, Bentolila et al., 2018;  
12 Greenstone et al., 2020; Farinha et al., 2021; Gutierrez et al., 2021). Within this literature,  
13 some of the most influential papers are summarized in Table 3 and Table 4. We split this  
14 branch of the literature into two different approaches: a) credit supply shocks and their  
15 effect on employment at an economy level (Benmelech et al., 2011; Giroud & Mueller,  
16 2015; Hochfeller et al., 2015; Greenstone et al., 2020; Gutierrez et al., 2021) and b) credit  
17 supply shocks and their effect on bank and firm financing relationship (Chodorow, 2014;  
18 Popov & Rocholl, 2015; Acharya et al., 2018, Bentolila et al., 2018; Farinha et al., 2021).  
19  
20  
21  
22  
23  
24  
25

26  
27 **(Insert Table 3 here)**  
28

29  
30 Giroud & Mueller (2015) and Greenstone et al. (2020) investigated the effects of  
31 the global financial crisis of 2007-8 on employment of the United States. Greenstone et al.  
32 (2020) reported that states with banks that cut lending affected small business employment  
33 growth rates by 0.6%. To determine whether this effect is supply-driven, they separated  
34 states with more Citigroup branches than US Bankcorp branches and found out that only a  
35 small percentage of small business employment reduction could be explained. They  
36 deduced that credit supply shocks contributed to real economy outcomes during the Great  
37 Recession, but its effects were modest. Giroud & Mueller (2015) investigated this  
38 relationship by using real estate prices of 2006 (prior to the crisis) and 2009 (during the  
39 crisis) and measuring employment change during those years. They found that a 1% decline  
40 in house prices is associated with 0.053%-0.068% drop in employment.  
41  
42  
43  
44  
45  
46  
47  
48

49  
50 Benmelech et al. (2011), Hochfeller et al. (2015) and Gutierrez et al. (2021) analyse  
51 on a scale more specific than the country level how credit supply shocks affect employment  
52 during different time periods. Benmelech et al. (2011) examined the impact of the decline  
53 in real estate prices in Japan during the 1990s on the U.S. economy through the contraction  
54 of loan supply by U.S. affiliates of Japanese banks. In their analysis, they found out that  
55  
56  
57  
58  
59  
60

1  
2  
3 these banks had a decline in credit supply in the US concurrently with the drop in real estate  
4 prices in Japan. Using this as a first stage in a two-staged model, they find that metropolitan  
5 statistical areas' unemployment increases by 1% when there was a contraction in Japanese  
6 affiliated bank lending following a real estate decline. Hochfeller et al. (2015) examined  
7 how employment reacts in different Germany states to Landesbank's trading losses in US  
8 securities. Indeed, according to their results, states affected by credit supply shocks  
9 experience a 0.8-0.9% reduction in part-time and total annual employment growth. Finally,  
10 Gutierrez et al. (2021) analyse domestic credit supply shocks in each labour market in  
11 Mexico and how they affect their employment growth. **In contrast to prior research, they**  
12 **place more emphasis on positive shocks, and their findings reveal that** a positive credit  
13 supply shock of one standard deviation, increases yearly employment by 0.45% when  
14 compared to labour markets with no credit supply shocks. Moreover, they find that this  
15 increase is mostly attributed to employees in the upper half of the wage distribution.  
16  
17  
18  
19  
20  
21  
22  
23  
24  
25

26 As for credit supply shocks and their effect on bank and firm financing relationship,  
27 the primary paper that investigated this relationship was that of Chodorow (2014).  
28 Chodorow researched the effect of syndicated loans **on firms' employment during the**  
29 **Global Financial Crisis**. In a syndicated loan, the main lender set up a loan deal with a firm  
30 and provide the majority of the financing while secondary lenders provide the remainder  
31 of the funds. Chodorow **observed that firms engaging in relationships with less healthy**  
32 **banks during the pre-crisis** had lower possibilities of acquiring a loan after the Great  
33 Recession and reduced employment more compared to firms that had relationship with  
34 healthier lenders.  
35

37  
38  
39  
40  
41  
42

43 **(Insert Table 4 here)**  
44

45 Based on the logic of that seminal paper, many researchers **henceforth** investigated  
46 how employment **fluctuates** focusing on specific bank characteristics. For example, **Popov**  
47 **& Rocholl (2015) differentiated between banks impacted by the US mortgage crisis and**  
48 **those unaffected** and investigated whether firms that had a financing relationship with  
49 either group was affected significantly. They concluded that firms with bank relationships  
50 to banks affected by the US mortgage crisis reduced employment by 2.2% relative to firms  
51 attached to non-affected banks. Similarly, Acharya et al. (2018) researched **whether**  
52

54  
55  
56  
57  
58  
59  
60

1  
2  
3 dependence on GIIPS banks (Greece, Ireland, Italy, Portugal, Spain) affected firms'  
4 employment. In their results, they reported that firms in higher dependence on GIIPS banks  
5 experienced less growth in employment, approximately 4.1% less for an increase of one  
6 standard deviation to GIIPS bank dependence. Bentolila et al. (2018) focusing exclusively  
7 on the bipole of relationships with financially weak (saved by the Spanish government)  
8 versus strong Spanish banks, found out that firms with attachment to weak banks faced  
9 employment losses of about 2.8% higher relative to the other category of firms. Finally,  
10 Farinha et al. (2021) created a two staged model where the outstanding credit from EBA  
11 banks is measured, relative to other banks, to create a firm and bank match that is later used  
12 to measure employment change. A deterioration in the EBA index by one standard  
13 deviation is associated with a drop of 0.9% in employment. When firms are further  
14 categorized into single and multiple relationships with banks firms, they discover that the  
15 former entirely drives the effect.

## 29 **2.4. Financial Health Measurements and Employment**

31 The third and last category of employment and financial constraints is related to the  
32 use of balance sheet measurements as financial health indicators to measure employment  
33 growth and/or change. Within this literature, the most commonly used measurements are  
34 leverage and debt ratios (Hernando & Carrascal, 2008; Spaliara, 2009; Benmelech et al.,  
35 2011; Giroud & Mueller, 2015; Berton et al., 2018), profitability (Hernando & Carrascal,  
36 2008; Benmelech et al., 2011), liquidity and cash flow (Spalira, 2009; Benmelech et al.,  
37 2011 as well as collateral (Spaliara, 2009). While balance sheet measurements are not  
38 direct indicators of employment change in a firm, they can indirectly affect employment.  
39  
40 Concerning liquidity, companies with ample liquidity (high current assets to current  
41 liabilities) reduce their cash reserves following a credit supply shock. This allows them to  
42 absorb the shock without significant impacts on employment. However, firms with low  
43 liquidity need to increase their cash holdings when credit rationed, leading to potential cuts  
44 in assets that may hamper investment and employment (Berg, 2018).  
45

55  
56  
57  
58  
59  
60

1  
2  
3 In a similar note, high levels of debt can strain a company's financial resources,  
4 potentially leading to cost-cutting measurements such as layoffs to meet debt obligations.  
5 Under assumptions such as quasi-fixed labour or potential lag between labour input and  
6 production, firms may need to raise funds externally to finance labour (Spalira, 2009).  
7 Moreover, profitability enables firms to invest in expansion and R&D potentially fostering  
8 employment growth. As such, monitoring these measurements can provide insights into  
9 the overall well-being of a company and help anticipate potential variation in employment.  
10  
11  
12  
13  
14  
15

16 Within the context of a firm's debt influence on employment, Hernando &  
17 Carrascal (2008) analysed the responsiveness of employment to debt burden, indicating a  
18 a negative relation. Giroud & Mueller (2015) reported that firms which increased their debt  
19 levels in the run-up to the Great Recession exhibited a larger decline in employment from  
20 demand shocks compared to firms with lower debt levels. Duygan et al. (2015) focused on  
21 differences between small and large firms. Their research demonstrated that employees in  
22 small firms within industries characterized by high external financial dependence were  
23 more probable to become unemployed compared to workers of the same type in large firms  
24 during the financial crisis. Moreover, there was no significant differences in large and small  
25 firms with low external financial dependence in unemployment dynamics. Finally, Berton  
26 et al. (2018) reported that change in total loans by firms influence significantly employment  
27 layoffs at the firm level. This effect is attributed to small and micro firms and mostly in the  
28 service sector relative to industries.  
29

34  
35  
36  
37  
38

39 Regarding other financial health measurements, Spaliara (2009) examines how the  
40 capital to labour ratio responds to fluctuations in collateral, leverage and cash flow.  
41 Spaliara finds a negative effect of cash flow and leverage on the capital to labour ratio  
42 while collateral exerts a significant positive effect, stressing the importance of tangible  
43 assets in borrowing capital. Likewise, Benmelech et al. (2011) found a positive relationship  
44 of profitability and liquidity on employment growth.  
45  
46  
47  
48

### 50 **3. Conclusion**

51  
52  
53 In this paper we examine under a broader prism the credit rationing literature and  
54 its results on real economy. Specifically, we made a brief distinction between the effect of  
55  
56  
57  
58  
59  
60

1  
2  
3 credit rationing for both factors of production, namely capital and labour. We merely  
4 focused though our analysis on the main topic of this paper, the relationship of employment  
5 and credit rationing. We started by analysing the theoretical background that binds them,  
6 referring to the phenomenon of jobless growth and job reallocation due to financial market  
7 growth. We proceeded by making a within firm analysis and introducing the importance of  
8 financing in cases of mismatch between cash flow and labour costs, quasi-fixed labour  
9 costs and the indirect impact of credit rationing on employment through investments. We  
10 made a distinct reference towards SMEs, since these effects are exacerbated due to  
11 information opacity and lack of collateral that lead to higher likelihood of being credit  
12 rationed. Combined with the fact that SMEs don't have alternative sources of financing  
13 other than that of bank credit, the implications of credit rationing are further intensified.  
14  
15  
16  
17  
18  
19  
20  
21  
22

23 After introducing the framework of the relationship between employment and  
24 credit rationing, we clustered the relevant literature depending on the independent variables  
25 utilized. The first category we introduced was that of pure credit rationing and employment  
26 models. We further broke down this category into two segments, that of survey data  
27 analysis, that focused on credit constrained, discouraged borrowers and financial  
28 constrained measurements, and that of non-survey data analysis focusing on both the firm  
29 level and non-firm level.  
30  
31  
32  
33  
34

35 The second category we created was that of credit supply measurements and  
36 employment, analysing their relationship at economy and firm level. Generally, based on  
37 relevant literature, it is showcased that credit rationing, and credit supply fluctuations may  
38 hamper employment at a national level as well as at a firm level, affecting both large and  
39 small firms. The third and final category we created was that of financial health  
40 measurements (through balance sheet indicators) and employment where the relevant  
41 literature emphasizes on leverage and debt ratios that have been shown to have a negative  
42 impact on employment, while profitability, liquidity and cash flows a positive one.  
43  
44  
45  
46  
47  
48  
49

50 Albeit there are a vast number of papers regarding credit rationing and employment,  
51 the existing literature comes with its limitations and omissions. First, in credit supply  
52 literature where banks are divided into weak and strong through a variety of methodologies  
53 and data. It is important to consider and account for the possibility that healthy banks may  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 have collaborated with financially stronger firms relative to the weak ones. Failing to  
4 control for such characteristics may bias the estimation (Bentolila et al., 2018). Second,  
5 mostly evident in financial health measurements and credit rationing literature, is the issue  
6 of endogeneity. Variables measuring financial health like leverage and profitability are also  
7 correlated with firm's demand for labour. Likewise, financial availability and financial  
8 constraints measurements are correlated with demand for firm's final product or service  
9 which in turn influences its demand for labour (Benmelech et al., 2011). Third, a  
10 common characteristic in almost all studies researched, is the fact that there are no dynamic  
11 analysis models on the relationship of credit rationing and employment through time.  
12  
13  
14  
15  
16  
17  
18

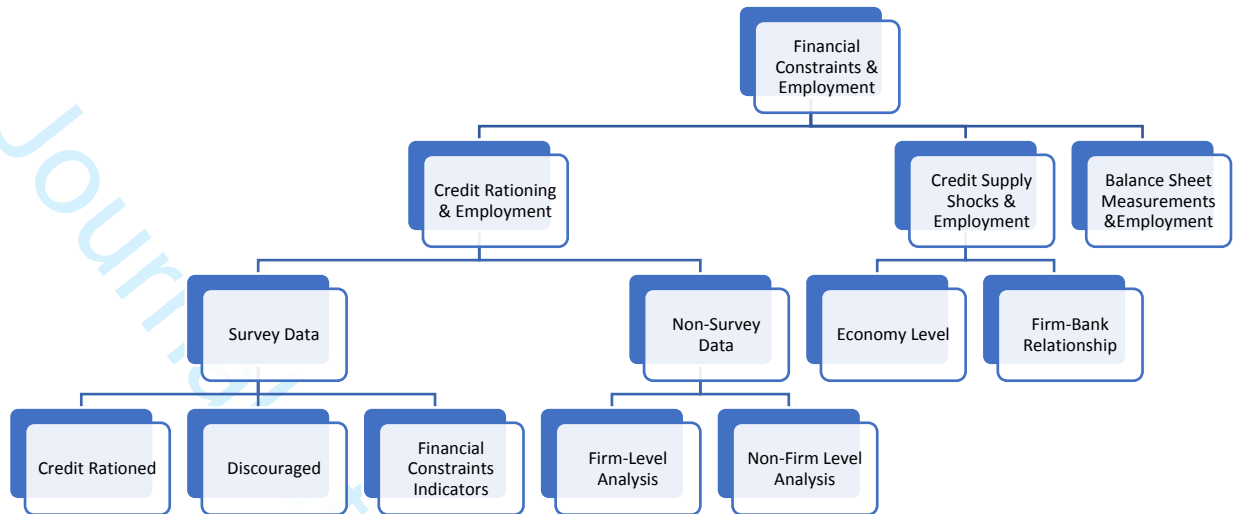

19 The implications of the findings are indeed interesting as they highlight the  
20 information inadequacies between enterprises and banks. Having established the  
21 importance of credit rationing in hampering employment, policymakers need to take  
22 measures in order to counter this problem, especially for the SMEs which are under a  
23 disadvantage relative to larger enterprises. Policymakers can employ a range of strategies  
24 to mitigate these issues, including enhancing information exchange among participants in  
25 the credit sector and expanding loan guarantee schemes. Policymakers must prioritise the  
26 development of policies that facilitate enterprises' access to financing, as it is crucial for  
27 their success.  
28  
29  
30  
31  
32  
33  
34

35 Especially for the case of SMEs, policy measures need to broaden the diversity of  
36 financing for SMEs by using also other forms of capital such as equity capital and  
37 encourage the use of innovative financial technologies (fintech). Usage of other forms of  
38 financing should help mitigate the over reliance on bank financing. Coupled with financial  
39 education initiatives, that will enhance the knowledge of firm owners and decision makers  
40 on how to enhance their firm's financial profile and creditworthiness, access to finance of  
41 firms can be improved. Furthermore, targeted policies for certain firms like credit  
42 guarantee programs for banks to encourage lending in SMEs, tax incentives for businesses  
43 that are expanding and interest rate subsidies to lower the cost of bank capital are crucial  
44 measures to promote growth within firms. Regarding collaborations, public-private firm  
45 partnerships can help foster a supportive environment for employment growth through  
46

1  
2  
3 synergies. Finally, policy making should emphasize on alleviating the informationally  
4 driven adverse effects on the employment decisions of financially constrained firms.  
5  
6

7           Regarding future study, there are multiple avenues to pursue. From our perspective,  
8 what still remains unclear is the specific factors that cause employment growth to be  
9 affected by credit rationing and especially the special case of discouraged borrowers. What  
10 requires examination is the modelling of the process that enterprises undergo in  
11 employment decisions within a context of self-rationed borrowers, using a formal  
12 economic model. It may be necessary for such a model to incorporate behavioural  
13 components in order to accurately reflect the firms' perception of prospective employment  
14 change.
